USES OF PSYCHO-THERAPY IN GENERAL MEDICAL TREATMENT *

By AUSTEN FOX RIGGS, M D,

STOCKBRIDGE MASS

A Definition

1 Psycho-therapy is mental therapy, therapy by mental means, not necessarily therapy directed against mental disorders. In short, it is treatment through the medium of the patient's consciousness.

2 The active principles of psycho-therapy are roughly suggestive and educative, or from another angle, the items of the patient's mind with which and through which it deals are suggestibility and educability. It has, therefore, roughly two avenues of approach, one leading to the emotional, the other to the intellectual side. Both sides are always affected, and the division is merely academic. Inasmuch as every human being possesses an emotional make-up and also an intellect, it would seem that these characteristics might be used to his advantage, no matter what the nature of his illness.

Indeed, the very make-up of "human nature" carries within it the warrant for psycho-therapy as at least an adjuvant item, or better, a guiding principle in all forms of treatment.

B Reputation

In ancient times psycho-therapy was probably the only, certainly the most important form of therapy, and, naturally, bore a high and honorable repute as white magic. But alas, as scientific medicine and surgery developed, mental treatment fell from its high estate, degenerated to a vagabond and consorted finally only with charlatans. It is only in the last two decades that its regeneration to respectability has gone far enough to warrant its readmission into the scientific family circle. That readmission has naturally been somewhat reluctant.

The most satisfactory and undeniable evidence that this readmission has really come about, that the general practitioner realizes the importance of psychiatry and the practicability in his own work

of its therapy is presented by the fact of this symposium on "Mind and Medicine" to which the Medical Society of the State of New York has invited a group of psychiatrists to contribute.

C Applicability to General Treatment

Medicine has, I think, thoroughly accepted the psychiatrist and neurologist as worthy and respectable specialists, but it is time now that the general practitioner should adopt some of their tried and proved wares into his own armamentarium. For if his patients one and all have emotions, and if disease both affects emotion and is affected by it, then he has only to realize that psycho-therapy, both as suggestion and education, will modify both of these reactions, to adopt it as one of his most important weapons.

II

EFFECT OF DISEASE OF EMOTIONS

1 Instinctive Reaction to Illness

I assume that no one will deny the existence of emotion in every human being, whether sick or well, so we may proceed without further delay to the second item of our thesis—the effect of disease on emotions, pausing only long enough to briefly and roughly define what we mean by emotions.

1 As human animals, our first reaction to any perceived change in environment is emotional, that is, it follows a biological and physiological pattern called inherent or instinctive. This process involves a distinct change in the physiological, bio-chemical, and mental status. The latter is that part of the change which is usually labelled "emotion." Or one might say, emotion is what we feel of instinctive reaction. This feeling is always more or less distinctly pleasurable or painful. But the emotion counts more than as pleasurable or painful feeling, for it always carries with it a more or less strong impulse to action, i. e., expression. If this impulse is carried out unmodified, or at least, unconsidered, we speak of the action as impulsive or instinctive.

* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse May 13 1925

If it is modified, or another action is substituted for it, according to the dictates of intelligence, then the action becomes considered or intelligent to a degree

Human animals, however, vary as to these two items. In the first place, some tend to over-react, some to under-react instinctively. Further, they vary in the relative strength of their specific instinctive tendencies. In other words, some people are more pugnacious, some more timid, some more aggressive, some more retiring than others, in response to any given condition.

In the second place, whatever their instinctive make-up may be and whatever degree of sensitiveness to its activities they may possess, they also vary in terms of their intelligence, thus they vary not only according to their instinctive reactions, but also as to their ability to modify these reactions. This variation may arise from a difference in fundamental ability to understand or from a difference in experience and training, or from a combination of both.

A third variant in personal tendencies is that called suggestibility. This is a tendency, widely varying in different individuals, to the uncritical acceptance of ideas. It is always present to some degree, greater in children and adolescents than in the middle aged, and least in the aged. Roughly speaking, in any one individual and about any one subject its strength bears an inverse ratio to the individual's specific knowledge of that subject. For instance, a layman is apt to be more suggestible than a physician in regard to a medical procedure. (This lay suggestibility always works for or against the physician.)

Thus every human being may confidently be expected to react to illness or any other perceived change in his environment according to

- 1 His instinctive and emotional make-up, including his general sensitiveness to these painful or pleasurable reactions.

- 2 According to the degree of his intelligence or his power, potential or acquired, to modify such reactions through understanding, and,

- 3 According to the degree of suggestibility he possesses, specifically in regard to the given change.

In short, no matter what the disease or disorder may be, every patient is to some degree timid or pugnacious, sensitive or insensitive, intelligent or stupid, and is to some degree ignorant or knowing, and he will react both to his disorder and also to his treatment accordingly.

B Effect of Pain and Discomfort

Irrespective of differences in individual make-up, pain or discomfort will have certain general effects on all.

In the first place, it will definitely increase the general emotional irritability. If the patient is naturally timid it will increase his timidity; if he is pugnacious it will increase that pugnacity.

In short, sensitiveness, whatever the specific or habitual experience may have been, will regularly be increased by pain.

Its effect on mood is of course well known. It diminishes elation or turns it into the channel of irritability. It definitely and directly causes depression. The classical physiological responses to pain are

- 1 Increased muscular tonus,
- 2 general increased psycho-motor activity,
- 3 marked vasomotor changes, and,
- 4 not infrequently sweating.

Among other items are the still little understood changes in blood chemistry, endocrine activities and metabolism. This, of course, is only the physiological side of the emotional picture. Perhaps these physiological changes constitute the actual specific basis of the emotion we feel in the presence of pain, complicated or not as the case may be, by the addition of specific fear or anger according to whatever may be one's particular make-up.

However this may be, the fact seems plain that pain has a specific effect upon the emotional status of one who suffers it, and that his response is likewise more or less specific according to his emotional nature, his suggestibility and his intelligence.

C Effect of Confinement

Inactivity, or better, *confinement*, is another aspect of illness or disability which calls for specific responses from the sufferer. By restricting the mental horizon, by forcing the attention to focus on pain, discomfort, or the abnormal function, it produces at least a strong tendency to introspection. Of course, merely mechanical confinement of a previously active person is productive of discomfort both of mind and body, not to speak of the boredom of an active mind thrown out of its occupation. Inactivity also necessitates physiological readjustments which add their quota of disagreeable sensations to those of the illness itself.

D Effect of Disability—Significance of Disease

Far more important than any of the foregoing items inherent in disease or disorder causing definite and unfavorable changes in a patient's emotional status, is what we may well call the *significance* of the episode to the patient. Indeed, if one includes a definite diagnosis of the individual make-up of the patient in the meaning of the term "significance" this one item may be said to contain the sum total of the psychotherapeutic, if not of the whole therapeutic indication.

The emotional effect of illness will depend largely on this item, for though the actual condition, be it a fracture of an arm, or pneumonia, is of obviously transcendent importance — its significance to the patient is far from being judged by the pain and discomfort which it may cause him.

That alone will produce some emotional reaction, but that reaction is a mere spark compared to the emotional blaze of his reaction to the significance which his illness has for him. A mere whisper produces a very small physiological reaction through the eighth cranial nerve, much maller than the loud, more painful sound of an explosion. Yet, if that whisper signifies that you are about to be shot through the head, the emotional reaction will be overwhelmingly great and extremely painful, whereas the loudest explosive sound, if you are sure that it only signifies a blast in a nearby stone quarry, can cause hardly more than annoyance. So it is with the pain or discomfort of illness, the absorbingly interesting question to the patient is, what is its significance? His emotional reaction is in response to some such category as this

What is the significance of these disagreeable symptoms?

Am I going to die or get well?

Does this mean a short or long invalidism?

How long and how much pain am I to suffer?

Am I to be disfigured, deformed, permanently crippled?

Will this effect my earning capacity?

Does this mean that I must assume a burden of debt?

Must I change or lose my job?

In other words, it is not the facts alone, but what the patient believes they are and what he believes they mean, which constitute their significance to him. Prognosis in the broadest sense of the word is, what interests him, and whatever he thinks it and feels it to be, is what he reacts to emotionally. To judge this significance, let alone to modify it favorably, one must know his patient, not just physically, but individually, that is, one must know his temperamental and instinctive make-up, the degree of his suggestibility, roughly, at least, his intelligence quotient, and his educational status, and last, but not least, his financial and economic condition. In short, to judge the extent and nature of any individual's emotional reaction to disease and disorder, it is of the utmost importance to know his individuality on the one hand, and keeping that in mind, to estimate the degree to which the condition seems to him to threaten his physical, his social and his economic integrity. Only by some such approach to his personal problem can one apply the often sorely needed psychotherapy. Aside from whatever individualistic differences they may exhibit, a banker with a large assured income who has suffered a simple fracture of the lower leg, obviously has a very different problem on his hands than a self-supporting woman suffering from the same or a very much lesser accident.

E Individualistic Variations of Reaction

However, given the same social and economic status and also the same illness or accident, very wide differences in reaction occur in different individuals. This is due as has already been suggested to fundamental differences in individuality. Obviously a highly suggestible, intelligent, though ignorant and perhaps superstitious and timid person will not only react quite differently to the actual disorder, but also will find a different significance in it, than, let us say, a non-suggestible, equally intelligent, better educated and somewhat pugnacious individual. It is quite obvious that each of these two hypothetical cases will have a different instinctive reaction to illness, this reaction will again be modified differently in each case, according to the available intelligence, each will react differently to the pain and discomfort, differently to the confinement, and lastly, and *most* differently, to whatever in each case is to him the significance threatening or otherwise of the illness.

III

EFFECT OF EMOTION ON DISEASE

A Functional Change is Basis of Emotion

As disease affects emotion, so conversely emotions must affect disease. After all, change in organic function is the very basis of emotion, and consequently there can be no change of emotional status without a concomitant change in organic function. Ergo, emotional change must affect disturbed as well as normal organic function, either beneficially or harmfully to some degree or another.

Anger, fear or pain as is well known, cause changes in the rate and character of the heart's action, in vaso-motor activity, in blood chemistry, endocrine activity, in gastro-intestinal action, and in muscle tone.

It is clear that these changes when they occur in the presence of diseases or disorders affecting any of the organs or so-called systems, must be either advantageous or disadvantageous.

B Diseases Affecting These Functions Must Then Be Affected By Emotion

No man of experience would care to have a patient suffering from high blood pressure undergo a violent and prolonged rage. Nor would he care to have a case of severe cardiac disease subjected to paralyzing fear, nor in fact, to any other violent emotion. What anxiety on the part of the nursing mother does to the baby is another obvious instance among many others which could be adduced to point the moral that emotions are by far too important factors to be neglected by a physician no matter what his specialty.

IV

EFFECT OF TREATMENT ON EMOTIONS

A Treatment Part of Situation of Illness

Entirely aside from any abnormal mental condition it is a fact that physical treatment itself is part of the situation to which a patient is adjusting himself. He reacts not only to the disease but to the treatment as well, not only to the significance of his disease, but, mark well, to the *significance of his treatment*, for no matter what is physically wrong he is always the sensitive emotional man, the more or less suggestible "child of nature," and his treatment, whatever its physical effect, has to him outstanding emotional and intellectual values.

B Environmental Effects

His surroundings are to him physically agreeable in terms of sight, sound and odor, or disagreeable. They are emotionally acceptable or repellant to some degree according to their significance to him. They may be gruesome, they may be threatening, or they may be hopeful and encouraging. These elements are always for or against his welfare, and should not be neglected.

This applies as well to the personnel by whom he is cared for. A good-looking attractive, friendly, interested nurse is as great an advantage as a homely, impersonal, uninterested nurse is a disadvantage.

C Significance of Procedures

So it is with all procedures, diagnostic or therapeutic, which the patient undergoes. Every item has its personal significance to him. We must not forget that in taking a history we are subjecting him not only to a memory test, not only to a disturbingly introspective process, but we are causing to pass in review before him many possibilities of familial and hereditary disease and weakness. A physical examination, likewise, may only too easily cause him to suspect as we do, each one of his organs as it is examined. He may well wonder, has he this disease or that? Perhaps he is fifty, and as often is the case, has long dreaded the possibility of cancer, or apoplexy, or heart failure, or arterial sclerosis. We may, furthermore, even introduce new suspicions.

Our therapeutic procedures also have special significance to him. How will this operation affect his life? Does it carry an immediate threat to life itself? Is he to suffer more pain and then be free from it? You may know the facts, but the chances are that without your help the patient does not know them, and they are the most important facts to him. If he is not informed, he will guess at them and react emotionally according to his guess. To give such information in practical and helpful form is a part, and a big part, of common-sense psycho-therapy.

V

PSYCHOTHERAPY

A Objects of Application

From what has gone before, the objects of applying psycho-therapy in general practice would then seem to be:

First, to avoid unfavorable emotional reactions,

Second, conversely, to foster favorable emotions,

Third, to build up favorable sentiments, such as courage and hope,

Fourth, to use favorable suggestion,

Fifth, to avoid adverse suggestion, and

Sixth, to gain intelligent cooperation, both in diagnosis and treatment, through the patient's understanding and his confidence.

B Understanding of Patient Essential Basis

In order to attain all or any one of these objects the first essential is to understand the individual one is dealing with, and that means understanding his instinctive personality, knowing roughly at least what his experience, educational and other has been, estimating with fair accuracy his intelligence, especially in terms of his educability and last, but not least, knowing his economic status.

C True Estimate of Significance (Disease and Treatment)

Only on some such basis can one reach an really practical estimate of the significance to the patient of his disease, or of the probable significance to him of the proposed therapeutic procedures. This estimate, at least a helpful guide to any treatment, is absolutely essential to any and all psychotherapy.

VI

APPLICATION OF PSYCHO-THERAPY

A Personal Attitude

When we consider the actual application of psycho-therapy, the personal attitude of the physician to his patient is of first and outstanding importance. It is in misfortune that "a feller needs a friend" and illness is a misfortune. This fact is an invitation to make the relationship of physician and patient one of friendship, and it is an invitation which must be accepted if psycho-therapy is to be successfully used. The wish to understand must precede understanding in order to lead to *sympathetic* understanding, and *sympathetic* understanding is as necessary to success as *unsympathetic* misunderstanding and contempt are destructive of it. Hence the importance of approaching the patient and his problem in the spirit of friendship. This spirit will show through the physician's manner more than in his words—so will the opposite. That highly personalized attitude of a scientist interested

only in the intellectual problem presented by a nameless "case" does not appeal to a patient. This, too, shows through both words and manner. Even if this does no other harm, it at least robs the patient of his sense of identity, which, by the way, if he happens to be a ward patient in a big hospital, is already pretty well shattered but it actually *does* do other harm, for this impersonal attitude repels confidence, and this puts an emotional dam where a bridge should be and thus excludes mutual and sympathetic understanding. Honesty of purpose and determination to succeed stand out in a physician's attitude and create confidence and hope, whereas vacillation, and that miserable self-protective covering of oneself from perhaps later having to acknowledge a mistake, by making all the other possible guesses and sharing one's doubts with the patient, is as contagious as any other form of cowardice.

3. *Useful Sentiments to be Aroused*

If we are to produce the useful sentiment of hope in our patients, we ourselves must be both hopeful and honest. If we wish to inspire faith we must not only be determined, one hundred per cent determined, to do our best, but we must have faith and show that faith in the integrity and ability of our patient.

If we are to inspire courage we must have it ourselves. These invaluable emotional aides or their harmful opposites, are absorbed by our patients more through intimation and unconscious imitation, more by indirect suggestion, than through didactic teaching and learning, and hereby hangs the great and constant importance in all forms of treatment or suggestion.

4. *Suggestion to be Used*

Suggestion plays a part all the time from the very first contact to the last. It acts rather through *how* a thing is done than what is done, through *how* a thing is said than what is said. A solemn and anxious manner will obviously completely neutralize an otherwise cheering phrase such as "First rate. You are doing well." Whereas the suggestive effect of a satisfied, confident and cheerful manner will easily carry off a literally cheerless remark such as, "Not so bad."

5. *Adverse Suggestions—Avoid*

To use suggestion and avoid adverse suggestion is largely a matter of that rare sense, common-sense and honest tact. Guided by sympathetic understanding, reinforced by the technique of honest tact, adverse suggestion can be avoided throughout all diagnostic and therapeutic procedures. The full advantage of favorable suggestion can likewise be secured through these same qualities by the simple method of emphasizing such diagnostic results as are distinctly

favorable—strong normal heart, a large lung expansion, for instance, and doing this same thing in therapeutic procedure by pointing out the results already attained or surely to be expected.

VII

APPLICATION OF PSYCHO-THERAPY TO SPECIFIC MENTAL STATES

A. *Many Diseases and Intoxications Accompanied by Marked Mental States*

There are emotional and intellectual disturbances caused specifically by infections and toxemias which in themselves constitute obviously important targets for our therapeutics. I refer to the hallucinations, the deliria, the elations and depressions so often occurring in the course of severe toxemias and infections, especially, if there is hyperpyrexia. These occur frequently and are at times quite threatening in themselves. It is so obviously important to be able to treat these mental conditions by mental therapy that stating the facts would seem sufficient argument for adding psycho-therapy to the general practitioner's equipment.

Typhoid, pneumonia and other infections and intoxications, if severe or if the patient is particularly sensitive, are not infrequently marked by specific mental states, which in themselves call for wise treatment. These states present definite opportunities for the general practitioner to apply common-sense psycho-therapy. Delusions, hallucinations, temporary or permanent changes in personality are seen in encephalitis, arterial disease and in cardiac-renal syndromes, these and exaggerations of mood as in the depression so often seen during and after an attack of influenza, are examples of such abnormal mental states and they occur with no little frequency in the course of general practice.

B. *Treatment (aside from physical) of These States*

The mental treatment of these states varies of course with the exact nature of the abnormality and its severity and, on the other hand, with the specific mental make-up of the patient. In general, however, it consists of the same elements (in varying proportion) which constitute all psycho-therapy, namely, suggestion and education.

Of course it is futile—not only futile, but harmful to force argument against a delusion. To fight it or to seem to fight it, merely antagonizes and distresses its victim. Realization of its reality to the patient is a *firm basis* for reassurance, and reassurance is sometimes more effective if made in the very terms of the delusion or hallucination. For example, if a patient sees spiders on the wall it is better to explain that they are harmless spiders or even go through the

form of wiping them off the wall, even if it has to be done over and over again, than to "pooh pooh" contemptuously the idea, which will only increase his distress and perturbation. Likewise, it is both futile and harmful to make a moral issue of a personality change and attempt to apply discipline thereto. The most careful, tactful, sympathetic, and skillful re-education and training, usually over a prolonged period, is necessary to produce a readjustment, whereas the mistaken "moral" method can result only in antagonism and hardening rebellion.

Mood swings must be intelligently, not forcefully, dealt with. To scold a patient for depression is to waste effort in proving to him what he already knows, that the depression is unreasonable, and simply increases the depression and further undermines his already shattered self-esteem. On the other hand, to teach him to accept it and its psychic pain as necessary though temporary evils which are characteristic of and due to his disease and not even distantly related to his moral integrity, helps him in the way he most needs and deserves help.

VIII

CONCLUSION

A Summary

To summarize

1 If any disease or disorder affects favorably or unfavorably to some degree the patient's emotional life, and, conversely

2 If the emotional state of any patient affects in some degree, favorably or unfavorably, whatever disease or disorder he may be suffering from, and furthermore,

3 If any form of treatment affects the patient, whatever his disease or his disorder,

somewhat through the medium of his mind,

4 Then, there can be no question that psychotherapy—treatment of and through the patient's mind—is indicated to some degree for all patients, whatever they are suffering from, and in all forms of treatment, whatever their nature.

5 Then there remains only the question as to how important in any specific case and in any particular procedure psychotherapy is.

I believe that it is measurably important in all cases and in all forms of procedure, both diagnostic and therapeutic, but that its relative importance is in direct ratio to the degree and specificity of the sensitiveness of each patient, and on the other hand, to the degree of significance which the procedure has for him.

6 The specific methods of psychotherapy are education and suggestion. The diagnostic guide to their application is the physician's understanding of his patient's individuality.

B Conclusion

Therefore, in conclusion, I wish to point out that though psychotherapy is, to be sure, often only "common-sense," it requires just as specific knowledge and just as specific training as any other therapeutic technique. This specific knowledge is psychiatry and it should, therefore, be given an important place in undergraduate medical teaching. Finally, I dare suggest psychiatry also as a post-graduate study, most valuable and profitable to the general practitioner. After all, psychotherapy applied to general practice is but the specific modification of all procedures to suit each patient's emotional and intellectual need. Its mastery will measure the physician's own educability, its application will spell the quality of his success in contributing to his patient's welfare and happiness.

MENTAL HYGIENE AND ITS RELATION TO GENERAL MEDICINE*

By C MACFIE CAMPBELL, M.D.,

CAMBRIDGE, MASS

The startling advances recently made in the knowledge and treatment of the infectious and the metabolic disorders have given special prestige to biochemical and immunological studies, the reaction of the individual to the demands of the environment has made less appeal to those of an exact turn of mind and insistent on laboratory methods of precision. The biological study of man, however, requires not only the detailed analysis of the component mechanisms but also of the reaction of the individual as a whole to the complex demands of the social environment. Physicians see many patients whose crippled condition is due to some hitch in their adaptation to the social environ-

ment, the physician who neglects altogether the situation in face of which the patient finds himself, or the personality which has to deal with the situation, may miss the key to the symptoms of his patient.

In regard to the great number of people who break down owing to some difficulty of adaptation to the environment, most definite recognition has been given to those with overt mental symptoms, the so-called "insane." These patients, however, represent only one group of mental disorders and not that group which the general practitioner has most contact with and most opportunity of serving. The fact that the State has to a large extent taken over the responsibility for the care of such patients, and that the patients are looked after in

*Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse May 13 1925

hospitals not much visited by the general practitioner tends to eliminate the care of these patients from the immediate field of interest of the practising physician. The general practitioner is more familiar with another group of mental disorders, composed of those which masquerade as physical disorders, while the roots of the trouble lie in the emotional and instinctive life of the patient. These patients may be seen by the psychiatrist, but usually only after a pilgrimage to many other physicians. Their experiences during this pilgrimage may do much to determine the persistence and the variety of the symptoms which they present.

It is well to include among mental disorders many cases of distorted or hampered personality. The physician, perhaps called in for some incidental sickness, if a student of human nature and mental hygiene, may find as much of interest in the patient himself as in his bronchitis or his gout. His attention is arrested by the special inefficiency of one patient, the ill-balanced enthusiasms of another, the rigid and reticent personality of a third, the individual likes and hates and mental attitudes of others. Marital incompatibility, strained relations between children and parents, various indications of an unhealthy atmosphere may be noted. It may be as reasonable for him to try to improve this atmosphere as it is to give directions with regard to the physical ventilation of a sick room.

There is no more important field in preventive medicine than that offered by the minor indications of personal difficulties in childhood.

In regard to the various groups of mental disorder referred to, the general practitioner has an opportunity of being of the greatest service.

Quite apart from his help to the individual patient, the general practitioner is able to do much to raise the level of thought of the community in regard to problems of mental health, he can encourage people to face squarely mental illness, to deal with it promptly and appropriately, and to look upon it in the same matter-of-fact way as upon other forms of sickness. When this is the general attitude of the community, patients with mental disorders will have a better chance of their troubles being thoroughly studied and adequately treated at an early period when most can be done for them. At the same time the dissemination of this point of view will remove the heavy burden of those who feel that they dare not even speak about their relatives who happen to have some mental disorder, and who shudder as they think of the bogey of heredity.

Similarly in regard to mental defect it will be an advantage when all false values are re-

moved from the topic and when physicians encourage the parents of backward children to recognize frankly their limitations and to arrange for the best development of the capacities of the individual child. How often do parents come in despair with adolescent defective children whose training has been unfortunately neglected owing to the sensitiveness and old-fashioned views of the parent!

To take up in some more detail the problems of the above groups from the point of view of the general practitioner

(1) Severe and protracted cases of mental disorder are, as a rule, treated in hospitals under the care of psychiatrists. In the incipient stages and with mild symptoms the patient may, for a long time, be under the care of the general practitioner. The latter feels at home in studying the physical symptoms of the patient and in instituting the necessary measures of treatment for any obvious somatic symptoms. He has more diffidence about trying to make a specific analysis of vague changes in mood, of slight peculiarities of social behavior, of special subjective complaints of the patient. He may not know how to examine in a systematic way and with precision the functions through which the individual adapts himself to the environment. He may not know how to review the personality of the patient, nor how to analyze the rôle played by the instincts, the special attitudes, the phantasies and memories of the patient, nor what weight to lay on the stresses and strains of the life situation. The physician has been trained to study the behavior of the heart under various circumstances, he has seldom been trained to study the behavior of the individual. The medical examination of a patient is incomplete unless the physician has paid some attention to the emotional life of the patient, and to his main attitudes and beliefs. Mental disorders are not always symptomatic of infections or disturbed metabolism. They are frequently symptomatic of the difficulty which the individual has in digesting painful experiences, in assimilating disturbing instincts, in facing the objective world without any pleasure-giving distortion. Psychiatry has only begun to free itself from the shackles of a complicated jargon which has done much to intimidate the general practitioner, what with schizophrenia and paraphrenia, schizoid and cycloid, extravert and introvert, he feels that a psychiatric diagnosis is either a most alarming intellectual effort or largely bluff. The physician who realizes that the technical verbal diagnosis of the condition is of secondary importance and who passes beyond the verbal diagnosis to the real difficulties in the life of his patient, who studies earnestly the latter's life problems

and equipment for dealing with these problems, can be of great practical service to the patient. It is difficult to over-estimate the relief which is given to a patient who finds a physician willing to give time for the consideration of his personal difficulties and to whom he can unburden himself. Such an opportunity for a serious discussion is half of the treatment and can be utilized without the aid of technical jargon.

(2) The general practitioner, while feeling at a loss in face of an overt mental disorder, is less puzzled when confronted with patients who do not have any distorted ideas of the outside world, who have no feeling of being under a mysterious influence, who have no hallucinations and who do not want to commit suicide, but who complain of a great variety of attacks or symptoms, for which no adequate organic basis is found. He groups them together as "nervousness" or uses in a rather rough and ready way such terms as "hysteria" or "psychoneurosis." Physicians of one temperament consider such patients from the ethical standpoint, apply the term "neuropathic" in a derogatory sense, have little interest in the actual mechanism of the symptoms of the patient, their interest in the case ceases when they have made the diagnosis "hysterical" or "functional." In others therapeutic enthusiasm leads to a definite line of treatment, either original or borrowed from one of the schools, and the physician realizes that his personal interest and sympathy have much to do with the attainment of good results. There is no reason, however, why the general practitioner should not attempt to make as accurate a diagnosis of these patients as of his cases of heart disease or kidney trouble, he is not content to diagnose one of the latter group as having some vague "cardiopathy" or "nephropathy," he must be equally unwilling to think of one of the former group as having some vague "neuropathy" or "psychoneurosis." When he uses the term "hysteria" in a strict sense he must realize that it is not only a negative diagnosis eliminating an impersonal organic basis for the symptoms, it is a positive diagnosis involving a specific mechanism which explains the development of the individual symptoms under the influence of the definite situation. It is only when this mechanism is clearly grasped that treatment will be adequate. Here again the general physician may feel rather intimidated by the extraordinary complexity of psychological mechanisms, made still more alarming by names borrowed from Greek mythology, but as he diagnoses and treats his heart cases efficiently without having exhausted the details of the electrocardiogram, so he may treat many cases of hysteria, of phobias, of obsessive thinking without a highly

specialized knowledge of the psychological underworld.

(3) It is well to restrict such terms as "hysteria" and "obsessions" to cases presenting certain special mechanisms. There is in addition a large army of patients with physical symptoms, in whom personal factors play an important rôle, while the physical systems also are partly at fault and supply some ammunition for the personality. In these cases the question is not whether the handicap of the patient is due to mental or to physical causes (or preferably to simple impersonal or complex personal causes), but *how much* is due to the former and how much to the latter. In a great number of so-called "nervous" cases or cases of "nervousness" some physical anomalies are found and require attention. There is a tendency on the part of those engrossed in the study of the more complex functions to neglect the simpler functions, to give inadequate attention to nutrition, to the oral hygiene, to gastro-intestinal conditions, to the necessity of fresh air and sunshine and a well-balanced daily program. There is on the part of others the tendency to lay all the stress upon the physical disorders present and to pay little attention to the more complex factors, or to look upon them as merely symptomatic of the physical condition and not deserving of independent study. With slight hyperacidity the patient may be encouraged to devote a good deal of time and attention to it, while the complete neglect of the gastric symptoms with attention to certain domestic or social problems or a review of past experiences might lead to a better result. So the patient may be encouraged to lay too much emphasis on the blood-pressure, weight, posture, minor aches and other subjective feelings.

(4) When general medicine takes the patient himself as an object of study and looks upon his happiness and efficiency as of some importance, various personal conditions will become objects of medical scrutiny which tend, at present, to be considered as outside of the problems of the physician. The physician is entitled to correct bad physical posture, it is not looked upon as equally obvious that he should do what he can for a bad mental attitude. A person with a faulty posture may have no pronounced symptoms but the orthopedist may see how a little advice may enable the patient to use his energy more economically and with less fatigue. The patient, after utilizing such advice, may realize for the first time what it is to be in good health and may look back upon his previous condition as one of ill-health, not recognized at the time as such. So there are plenty of people rubbing along in life with no outstanding symptoms of the type which we ordinarily associate with mental

illness, but who are essentially in a condition of ill-health or reduced health, and who might utilize their equipment much more efficiently and get a great deal more happiness out of life. It is hardly possible to enumerate the different personal complications, the special prejudices, the special topics of sensitiveness, the unsatisfactory compromises and defense reactions which may interfere with full efficiency and happiness. Many people are living in one situation, *as if* they were in another, they are living in their adult life, *as if* they were still facing a situation of childhood, they are living in relation to one person, *as if* he were another, the emotional values they give to situations may have little relation to the actual situation, but are derived from that other imaginary or past situation in which their attitude finds its explanation. The married man finds things unsatisfactory because unwittingly he is looking for a mother when he has in fact taken a wife, and so the wife may feel a strange discontent because she does not find in her married life the comfort of a daughter-father relationship. The radical behaves to the state authorities *as if* they were his own tyrannical father. The parent treats the child *as if* the child were he himself having a second chance at life. The prudish young woman feels that others are very unsympathetic and critical, because she sees others *as if* they were inspired by her own self-criticism and discontent. The adult is still weighed down by a feeling of inferiority or may compensate for it in a disagreeable way, *as if* the early criticism of childhood misdemeanors were absolutely valid and final and *as if* he were inferior to others. The situation which brings the physician into the home is infinitely varied. It may be a mental disorder, it may be a so-called nervous condition, it may be some organic condition of heart or gastro-intestinal tract, or it may be because the individual in despair at working out his own salvation turns to the physician to see whether he has anything to offer. No matter what the initial reason for the contact may have been, the physician, if sensitive to the main issues of life, may give advice in regard to problems which are of far greater importance than those which first brought the patient to the physician. A mother may bring a child because of some trifling symptoms of the child which puzzle her. She may stay to get a better philosophy of life and to realize that her solicitude for the child was merely one indication of her own difficulty in meeting her own problems. A teacher may come because of some apparently minor variation in teaching efficiency, and may find that it indicates a variety of unsolved problems which it is worth while trying to solve. A man may come in a very critical attitude to discuss his wife's be-

havior and have his eyes opened to the real problems of his own life. The individual may come for some minor symptoms, some trifling eruption or subjective feeling or minor speech defect, and may find that the symptom is of little importance while the personal problems behind the solicitude over the symptom are worth attending to.

(5) The increasing attention to the needs of the child has brought many children to the physician in a way previously unknown. Mothers wish advice, not only about the diet of their children and hours of sleep, but about their training about how to develop kindness and unselfishness, concentration and efficiency of all kinds. The systematic survey of school children has given the physician the opportunity of reviewing large groups systematically and of coming across problems which would otherwise have escaped attention. It is possible to estimate the mental hygiene of many homes as we have previously studied their physical hygiene. Some knowledge of the simple principles of the training of children is badly needed in many homes of rich and poor. It is not a question of social or economic or educational level, academic culture and great solicitude of parents are sometimes found along with absurd training of the children. The values given to topics in childhood are liable to persist into adult life, and seriously faulty adult attitudes may have their first beginning in early childhood. Insurmountable difficulties in adult life might have proved very ordinary tests had the early training been different.

The general medical profession can make a valuable contribution to the mental health of the community by taking the personality of the child and its disorders of conduct as seriously as it takes its difficulties of nutrition and infectious disorders.

Every physician is an unofficial guardian of the public health and in his own practice can be an important force for good in the enlightenment of the community. Many are chosen to play a special rôle in relation to certain large organizations. The physician is called in to advise the school system with regard to the health of school children, in industry he is in touch with large groups whose health he is responsible for safeguarding. As a municipal and state officer he can do much to guide the thought of the community in regard to health problems. In all this work it is very important that the physician should never forget that the highest aim of medicine is the efficiency and happiness of the individual and that this aim can only be accomplished when attention is paid to the complex factors involved in human nature and to environmental opportunities out of which human nature must wrest its satisfaction.

THE VALUE OF BLOOD TRANSFUSIONS IN POST-OPERATIVE MASTOID CONDITIONS WITH SPECIAL REFERENCE TO SUSPECTED SINUS THROMBOSIS *

By HAROLD HAYS, M.D., F.A.C.S.,

NEW YORK CITY

WITHIN recent years the methods for transfusing blood have become so simplified and standardized that blood transfusion has become a therapeutic procedure, which is second to none in the treatment of certain conditions. The indications for transfusion are in hemorrhage, diseases of the blood, toxemias, infections, shock and general debility. There are no contra-indications.

An historical survey of the methods for transfusion is not without interest. As short a time as fifteen years ago, direct vein to vein or vein to artery anastomosis was the only method known. The operation was tedious, technical and took hours to perform and, often it was attended with certain dangers because methods of typing the blood were unknown. Moreover, it was impossible to estimate the amount of blood which the patient was receiving. From then on a gradual evolution in methods took place. The greatest advance was made by Lindeman, of New York City, who demonstrated that blood could be transferred from recipient to donor by the use of multiple syringes. In this way the patient could be conveniently placed away from the donor, and the amount of blood which was transfused could be determined. In the meantime, better methods of typing the blood were discovered, until today we can accurately match donor and recipient. It was but natural that a class of professional donors should come into existence, healthy individuals with no evidence of syphilis or any other blood disease, who had been previously classified, and who could be called to service at a moment's notice.

Various modifications of Lindeman's method have been described from time to time. Each one has its value. But the simplest of all the methods, and the one which is bound to meet with universal approval because of its simplicity is the one devised by Dr. Lester J. Unger of New York City, in 1915. A description of the instrument and technic follows.

Fundamentally the instrument is a stop-cock, which alternately connects a syringe for blood to the donor, and at the same time a syringe with saline to the recipient, by turning the cock, the syringe with blood is immediately connected to the recipient and the syringe with saline to the donor.

Alongside of the instrument, which has been fixed to a table, the arms of the patient and donor are placed. The tubes leading from the

instrument are connected to the cannulas after the latter have been inserted into the recipient's and donor's veins. The operator then inserts a record syringe into the instrument and aspirates blood. When the syringe is filled, the assistant turns the stop-cock and the operator injects the blood. This is continued until the desired amount has been transfused. By means of an ether spray, a stream of ether is played on the barrel of the record syringe while it is being filled with and emptied of blood. This prevents coagulation.

The syringe method of transfusion has definite advantages which make it a method of choice when a transfusion of whole unmodified blood is desired. The method is extremely simple. Any amount of blood may be transfused with but one syringe and unusual dexterity of the operator is unnecessary.

I do not wish to enter into a controversy as to the relative merits of whole blood and citrated blood (blood treated with a 2% sodium citrate solution, so that it may be kept outside the body for an indefinite length of time). Much as citrated blood is of value for replacing blood lost from hemorrhage, for example, there is no question that unmodified blood is far more valuable in the cases which will be considered in this paper.

Only within the past few years have we been in a position to realize the great value of blood transfusions in complicated post-operative mastoid cases. In 1920 there was actually an epidemic of mastoiditis in New York City. Ninety per cent of children who developed an acute infection of the middle ear eventually developed symptoms of mastoiditis, and many of these had to be operated upon. To add to the distress, the majority of these children developed some sort of complicating condition which ranged from a prolonged convalescence caused by the severity of the original infection to sequelæ such as sinus thrombosis, brain abscess and meningitis. The cases which baffled us the most were those in which there were intermittent temperatures, often rising to 106 degrees F suggestive of a sinus infection, but in which the blood cultures were negative, and there were no other signs of vein infection. The problem was not so difficult of solution where there had been an operation on one side only, for one could, with justice, reopen the mastoid wound, uncap the vein and investigate it. But where there had been a bilateral disease and operation, it was often impossible to determine which side might

*Read at the Annual Meeting of the Medical Society of the State of New York, Syracuse May 13th 1925

possibly be causing the trouble and one had to wait for the presentation of definite symptoms. Having two baffling cases at that time, it was suggested to me that both these children be transfused. A citation of these two cases will prove of interest. **CASE 1** A child of three years had a bilateral otitis media. The discharge had continued for three weeks with irregularly high temperatures, until definite signs of mastoiditis developed. The infection was due to the streptococcus hemolyticus. Both mastoid processes were thoroughly cleaned out. Neither sinus or dura was exposed on either side. After the operation, the child developed intermittent temperatures as high as 106 degrees F with chills. Numerous blood cultures were negative. The blood count at one time was 50,000 leucocytes with 86% of polymorphonuclear cells. There was a suspicion of broncho-pneumonia. The child's condition was so bad that a transfusion of 400 c.c. of blood was given her. Immediately, there was an improvement and, although pneumonia eventually developed, she was able to ward it off without any trouble.

CASE 2 A boy, four years of age, developed a bilateral mastoiditis, the infection caused by the streptococcus hemolyticus. At the time of operation great difficulty was encountered because the sinus plates were directly underneath the cortex and both sinuses were exposed. A few days after operation the child began to run intermittent high temperatures. On the fifth blood culture organisms appeared on the culture media, and a doubt as to a sinus thrombosis was cleared up. The question then arose as to which sinus was involved and, after numerous consultations, it was decided to investigate the right sinus and, if infection was found, the jugular vein was to be ligated. This sinus proved to be affected, and so the ligation was done. In spite of this, the temperature continued and an infection of the right ankle occurred. This was opened up, but the temperature still continued and there seemed to be a great possibility that the other sinus was involved. At the end of the third week, the child was given a blood transfusion of 400 c.c. Within twenty-four hours, the temperature dropped to normal and remained there, and within a short time he was able to leave the hospital perfectly well.

These two cases were very instructive and proved the value of blood transfusions. In the first case, I have no doubt many surgeons would have uncapped the sinuses much to the detriment of the child. If the transfusion had not been performed, I feel sure that she would have succumbed to the pneumonia which remained hidden for such a long time. In the second case we were dealing with a septic temperature after the ligation of one jugular vein. There was a great possibility that the other vein was infected. The positive blood cultures after the first operation

may have been accounted for by the infection of the ankle, but they may also have been due to a diseased vein. The investigation of this second vein no doubt would have resulted in death. The blood transfusion allowed the child to withstand the infection and eventually ward it off.

But, to my mind, far more interesting than these cases are the ones where patients run a septic temperature after a mastoid operation where sinus thrombosis is suspected, but cannot be proved, and where an investigation of the sinuses would be a serious menace to the patient, particularly if both mastoid processes had been operated upon and no determination could be made as to which sinus might be causing the trouble. With all the evidences of a septic condition, most of these cases have repeated negative blood cultures. I have emphatically stated a number of times that I do not believe that one is justified in opening a sinus as long as the blood culture is negative. I do not mean by this that no sinus infection is present, but as long as the blood cultures are negative, nature is doing all that is possible, and in many cases it is possible that a clot forms in the vein which eventually cuts off the infection from the general circulation. But the evidences of infection must be overcome in some way, for although most of these patients will recover after a stormy and prolonged convalescence, the probabilities are that they will be much devitalized. In such cases, transfusions have proved ideal. I shall cite two cases to illustrate this point.

CASE 1 About three years ago, I operated upon a little girl of eight years for bilateral mastoiditis. The disease had been present for some days before consent for operation was given, with the result that there was severe destruction on both sides and both sinuses were exposed. On the tenth day after operation, the child had a rise of temperature to 106 degrees F with a chill. Investigation showed a peritonsillar abscess on the left side which opened by itself with a subsidence of the temperature. The child left the hospital a few days later apparently in good condition. The day she got home, the temperature rose again. An intermittent temperature took place for four days in succession during which time the blood cultures remained negative. Was a sinus thrombosis present? On which side was it? Because of the negative blood cultures, I refused to explore the sinuses. I sent her back to the hospital on the fifth day, and had a transfusion performed from the father. The temperature dropped to normal and never rose again.

CASE 2 At about this same time, I was caring for a most puzzling post-operative mastoid case. Miss F. M., age 39, had developed an acute mastoiditis which offered no great difficulties at the time of operation. The sinus was not

exposed. At the end of the tenth day, she left the hospital apparently well. A few days later her family physician informed me that she was running a low irregular temperature. Suddenly she developed a temperature of 104 degrees F with a distinct chill. For the following two days the temperature was normal and then it rose to 104 degrees again accompanied by a chill. This same phenomenon occurred a number of times. The blood cultures were always negative. The blood count showed 6,000 white blood cells with 60% of polynuclears. Two internists examined her carefully for a possible malaria or typhoid fever. As she complained of pain below the mastoid wound I thought it best to open the wound. It was found to be clean and healthy. Between the rises of temperature, the patient felt well enough to be out of bed and to do some of her clerical work. There was never any definite headache, and her general condition did not seem to suffer. Eye examinations, nasal examinations, gynecological examinations were all negative. There seemed to be nothing to do other than to watch for some definite symptoms of sinus involvement. The case seemed to be one to be classified under the heading of 'protein fever' (whatever that may mean). Finally, after three weeks, I suggested a transfusion from her twin brother. About 500 c.c. of blood were given her. The following day, the temperature rose to 103 degrees, then returned to normal, where it remained until she was discharged from the hospital a week later. There has never been the slightest evidence of trouble since then.

These two cases indicate very clearly that blood transfusions should always be given in any cases in which there is an unexplained temperature after an operation upon the mastoid process. If the transfusion does no more than tone up the general system, so that the patient is able to withstand a further operation better, it will have accomplished a great deal. In pronounced cases of septacemia of otitic origin, after the jugular vein has been ligated, transfusion will often be able to give the necessary tonic to the blood and this is particularly so if the donor is immunized with the particular organism which is causing the infection in the recipient. Unger is doing some excellent work along these lines. In a later paper (*The Laryngoscope*, February, 1923) he concludes, "Many patients with a positive blood culture (after sinus operation) can be cured by blood transfusion. Blood of an ordinary strong, healthy individual is usually not sufficient. For these patients a donor should be used whose phagocytic index is high. The donor should be immunized by injecting huge doses of a vaccine prepared from the organism isolated from the patient's blood. While this autogenous immune donor is being prepared, the patient should be supported by one or more transfusions of blood from a heterogenous immune donor." I saw one

case, a patient of Dr. Daniel S. Dougherty, who was eventually cured in this way.

From the citation of the above cases, one is led to feel that whenever a double mastoid operation has been performed and evidences of sepsis develop after the operation, the safest and best procedure to resort to, especially if repeated blood cultures are negative, is a blood transfusion. But even more absorbing and interesting than these cases are the ones in which there is a positive blood culture and distinct evidences of a thrombosed condition of the vein. The question comes up as to which vein is involved. Certain symptoms may indicate one side or the other. One vein may have been more exposed than the other at the time of the original operation. The patient may have a rigidity of the neck on one side. Examination of the eye grounds may show an engorgement of the retinal veins on one side. If one wishes to investigate further by reopening and exposing the sinuses, he may find a more diseased condition on one side than on the other. If he is still in doubt he may penetrate the vein with a needle and withdraw some blood in a sterile syringe, send it to the laboratory and find out on which side there is a growth. On the other hand, he may surmise that either vein is at fault or, at the time of the second operation, he may find that one vein looks as bad as the other. Surely one does not want to run the risk of ligating the wrong vein or ligating both veins. At the 1923 meeting of the American Laryngological Rhinological and Otological Society, Dr. Harold G. Tobey, of Boston, reported a case of double sinus infection on which the sinus was opened by him on both sides. He observes that a careful review of the literature since 1896 reveals only three other cases of actual obliteration of both sinuses. In one of these cases, the left sigmoid sinus was opened and a thrombus removed without the jugular vein being tied off. Five days later a thrombus was removed from the right side and the jugular vein of that side ligated. The patient recovered. In a second case it would appear that both sinuses were opened without positive evidence of a clot and without ligation on either side and the patient recovered. In a third case, the right sinus was incised about three weeks after the primary mastoid operation and the jugular vein of that side tied and partially resected. No clot was found and there was free bleeding from the sinus. The left sinus was then incised and packed, but the jugular vein was not ligated. This patient recovered. Dr. Tobey's patient was subjected to a double mastoid operation, April 25th, 1918. Four weeks later the right sinus was opened and the internal jugular vein ligated. Six days later the left sinus was incised and packed off, but the jugular vein was not ligated, and after a prolonged illness this patient recovered. It should be noted that in

these four cases only one jugular vein was ligated. In the light of the more recently reported cases of recovery from lateral sinus infection in double mastoid cases wherein it was impossible to determine which sinus might be involved, it is a question whether, in the four cases enumerated above, the patients might not have recovered without being subjected to the extreme danger of opening both sinuses (Wendell C Phillips, *Jour of the A M A*, August 25, 1923)

I have felt for some time that blood transfusion would solve the problem of recovery in cases in which there was a positive blood culture, where it was impossible to determine which sinus was involved or if both sinuses were involved. During the past six months, two cases were under my care which proved to me that a transfusion should be performed in all doubtful cases, and that possible transfusion would make operative interference unnecessary. A citation of the cases follow. **CASE 1** A little girl of eight years was operated upon for bilateral mastoiditis. Both mastoid processes were the seat of very extensive pathological processes. Both sinuses were exposed. They appeared to be healthy. The temperature after the operation returned to normal on the fifth day, but then rose to 106 degrees and was accompanied by a chill. The third blood culture showed the presence of the streptococcus hemolyticus on the blood plates. The question then arose "Which sinus was involved?" Consultations were held, but no determinations could be made. An exploratory operation was decided upon. The vein on the right side which seemed more diseased at the time of the original operation, was first exposed. The wall of the vein appeared diseased. It seemed wise to open this sinus. At once there was a profuse flow of blood from both ends. The vein was packed and the other sinus investigated. This second vein looked as bad as the first one, but it was deemed wise to defer any further investigation. Neither jugular vein was ligated. Within twelve hours, the child was given a direct transfusion of 400 c.c. of whole blood. Within a few hours the temperature returned to nearly normal and within a few days the febrile process subsided entirely.

CASE 2 A little boy of eight was brought to New York to have his tonsils removed. He had previously suffered from infections of the ears. Two days after the tonsil operation there was a rise in temperature and eventually an acute otitis media developed, the organism being the streptococcus hemolyticus. Six days after his original ear infection both mastoid processes had to be opened. The infection had spread so rapidly that both sinus plates were involved and the sinuses exposed. They appeared to be healthy. For a few days after the mastoid operations, the child seemed to be doing well and then an intermittent temperature occurred. Blood cul-

tures were negative for a time, but eventually one showed the presence of a few colonies of the same organism which caused the middle ear infection. The question again arose as to which sinus might be involved. At the time of the original operation one sinus did not seem any more diseased than the other. The wounds were reopened, but nothing could be found which would justify the opening of the sinuses. The result was that the child was put back to bed in the same condition in which he entered the operating room. The following morning he was given a transfusion of 400 c.c. of whole blood. Within a short time, the temperature began to subside, and eventually he left the hospital in excellent condition.

In the first case, one might feel that a mural clot might have been present on the right side, and that this was washed out at the time the sinus was opened up. This is possible, but I feel that we were dealing with a diseased condition of the vein wall, perhaps on both sides, and that the transfusion did more than the operation to relieve the child of her serious symptoms. I am convinced that the second case was cured by the transfusion.

At a recent meeting of the New York Otological Society, McFarland reported two cases of double mastoiditis in which there were typical histories of lateral sinus involvement, and it was impossible to determine which sinus might be invaded. In both of these cases, several transfusions were given covering a period of ten days to two weeks, and both patients recovered. The positive symptoms stated by McFarland are the typical temperature range, leucocytosis and bacteremia. Phillips in reporting these two cases, states that he considers it advisable to resort to blood transfusion at the earliest possible moment after a diagnosis has been made even though subsequent ligation should be determined upon. Children will bear 300 c.c. to 400 c.c. of new blood without any discomforts, while adults will need larger amounts. Sometimes two, three and four transfusions have to be given and, in severe cases, the immunized donor will have to be used.

Unger (*Jour of the A. M. A.*, December 27, 1917) says, "Transfusion is often of assistance in overcoming intractable suppurative processes and causing a marked increase in the vitality of the patient. In bacteremias it has had practically no success. It is possible, however, that if immune donors are used the results might be better. Transfusion given preliminary to an operation will often so improve the patient's condition that the surgeon is justified in risking an operation. It will prolong the life of a patient suffering with a debilitating condition." In contravention to Dr. Unger's statement I have seen two cases of sepsis and McFarland has seen two others which have gotten well when transfusions were given. It may happen that

the sepsis associated with sinus thrombosis is different from the sepsis from other conditions, such as endocarditis for example. In these cases we have a definite focus of infection which can be sealed off from the general system by the natural formation of a clot within the vein, so that the primary object is to raise the resistance of the patient which a blood transfusion does more rapidly than anything else. In a recent discussion on this matter, a prominent bacteriologist gave the explanation as follows: That although blood transfusions will not cure an acute septic condition, it has a decided ameliorating influence upon subacute and chronic sepsis. In most mastoid conditions the patient has been suffering from a prodromal infection and, by the time the mastoid process is operated upon, a certain immunity has been developed in the individual and the bacteria have lost some of their virulence. In other words one is dealing with attenuated bacteria. The result is that, when a transfusion is performed in these cases, the resistance of the patient is greatly and rapidly increased, and he develops enough antibodies in his blood to kill the bacteria which are floating in the blood stream. As long as few or no more bacteria are eliminated from the original focus, the patient will get well.

CONCLUSIONS

- 1 The Unger method of blood transfusion is the simplest and the easiest to use in complicated mastoid cases.
- 2 Many patients with intermittent temperature after a mastoid operation do not necessarily have a sinus thrombosis.
- 3 Transfusions are of the greatest value in baffling cases.
- 4 Transfusion of blood will increase the vitality of the patient to be operated upon for a complication and is of equal value after the operation.
- 5 In bilateral mastoiditis, when one cannot decide which sinus may be involved, a transfusion may make an operation unnecessary.

INSTRUCTIONS FOR USE OF THE UNGER TRANSFUSION INSTRUMENT

Articles Required (1) Two operating tables of the same level, or two beds, if the transfusion is done at the patient's home.

A board about 1 ft. by 3 ft. to be placed between the tables

A table for sterile materials

(2) An Unger transfusion apparatus and two Unger transfusion needles

One 20-cc. Luer syringe.

One 20-cc. Record syringe.

A No 17 French soft rubber catheter

Two artery clamps and one pair of scissors

Two tourniquets

Preparation Place the donor and recipient on the tables so that the head of the donor is opposite the feet of the recipient. Rest their arms on the board which is placed between the two tables. Sterilize the arms with iodine and drape properly with sterile sheets. On the central stopper of the stop-cock rub a very small amount of sterile vaseline. Work this in well by rotating the stopper several times.

Attach a 4-inch piece of a No 17 French soft rubber catheter (into which has been placed the curved connecting tip) to the recipient's outlet.

To the saline outlet, attach another piece of catheter

Attach the stop-cock to the pedestal and then firmly screw the assembled apparatus to that end of the board which is nearer the donor's head.

Technic The operator, who is standing next to the donor's head, places the cannulas (attached to the instrument) over the arms of donor and recipient. Move the arm, or even the entire body, so that the cannula lies parallel and over that part of the vein which is to be punctured. It is then certain that after inserting the cannula into the vein at this particular point no difficulty will be experienced in connecting the instrument to the cannula.

Via the saline outlet, force saline through both cannulas. Turn the stop-cock toward the donor. Put a tourniquet on the donor's and another on the recipient's arm. Insert the cannula into the recipient's vein (point it toward the heart). Remove recipient's tourniquet. After the assistant has injected saline to force out all air, the operator attaches the instrument to the recipient's cannula. From this time until the end of the transfusion the assistant continuously, but very slowly, injects saline. About one c.c. of saline is required to each 20 c.c. of blood transfusion. Insert the cannula into the donor's vein, pointing it against the blood stream away from the heart. Leave the tourniquet on the donor's arm. This direction of the needle gives the maximum flow of blood. If the blood spurts out of the cannula, connect it to the instrument. If the blood comes out drop by drop, do not make the connection. It is very important for the success of the transfusion to have a good flow of blood from the donor's cannula before connecting the latter to the instrument.

Insert the Record Syringe and aspirate blood. Turn the stopper and inject the blood. Continue this until the desired amount has been transfused. A nurse sprays ether on the outside of the Record Syringe. In this way only one record syringe is necessary, regardless of the amount of blood to be transfused. For this purpose use a small can of ether, in the top of which only one very small pin-point opening has been made. A hot towel wrapped around the can facilitates the spray.

the sepsis associated with sinus thrombosis is different from the sepsis from other conditions, such as endocarditis for example. In these cases we have a definite focus of infection which can be sealed off from the general system by the natural formation of a clot within the vein, so that the primary object is to raise the resistance of the patient which a blood transfusion does more rapidly than anything else. In a recent discussion on this matter, a prominent bacteriologist gave the explanation as follows. That although blood transfusions will not cure an acute septic condition, it has a decided ameliorating influence upon subacute and chronic sepsis. In most mastoid conditions the patient has been suffering from a prodromal infection and, by the time the mastoid process is operated upon, a certain immunity has been developed in the individual and the bacteria have lost some of their virulence. In other words one is dealing with attenuated bacteria. The result is that, when a transfusion is performed in these cases, the resistance of the patient is greatly and rapidly increased, and he develops enough antibodies in his blood to kill the bacteria which are floating in the blood stream. As long as few or no more bacteria are eliminated from the original focus, the patient will get well.

CONCLUSIONS

- 1 The Unger method of blood transfusion is the simplest and the easiest to use in complicated mastoid cases
- 2 Many patients with intermittent temperature after a mastoid operation do not necessarily have a sinus thrombosis
- 3 Transfusions are of the greatest value in baffling cases
- 4 Transfusion of blood will increase the vitality of the patient to be operated upon for a complication and is of equal value after the operation
- 5 In bilateral mastoiditis, when one cannot decide which sinus may be involved, a transfusion may make an operation unnecessary

INSTRUCTIONS FOR USE OF THE UNGER TRANSFUSION INSTRUMENT

Articles Required (1) Two operating tables of the same level, or two beds, if the transfusion is done at the patient's home.

A board about 1 ft by 3 ft. to be placed between the tables

A table for sterile materials.

(2) An Unger transfusion apparatus and two Unger transfusion needles

One 20-cc. Luer syringe.

One 20-cc. Record syringe.

A No 17 French soft rubber catheter

Two artery clamps and one pair of scissors.

Two tourniquets

Preparation Place the donor and recipient on the tables so that the head of the donor is opposite the feet of the recipient. Rest their arms on the board which is placed between the two tables. Sterilize the arms with iodine and drape properly with sterile sheets. On the central stopper of the stop-cock rub a very small amount of sterile vaseline. Work this in well by rotating the stopper several times.

Attach a 4-inch piece of a No 17 French soft rubber catheter (into which has been placed the curved connecting tip) to the recipient's outlet.

To the saline outlet, attach another piece of catheter

Attach the stop-cock to the pedestal and then firmly screw the assembled apparatus to that end of the board which is nearer the donor's head.

Technic The operator, who is standing next to the donor's head, places the cannulas (attached to the instrument) over the arms of donor and recipient. Move the arm, or even the entire body, so that the cannula lies parallel and over that part of the vein which is to be punctured. It is then certain that after inserting the cannula into the vein at this particular point no difficulty will be experienced in connecting the instrument to the cannula.

Via the saline outlet, force saline through both cannulas. Turn the stop-cock toward the donor. Put a tourniquet on the donor's and another on the recipient's arm. Insert the cannula into the recipient's vein (point it toward the heart). Remove recipient's tourniquet. After the assistant has injected saline to force out all air, the operator attaches the instrument to the recipient's cannula. From this time until the end of the transfusion the assistant continuously, but very slowly, injects saline. About one c.c. of saline is required to each 20 c.c. of blood transfusion. Insert the cannula into the donor's vein, pointing it against the blood stream, away from the heart. Leave the tourniquet on the donor's arm. This direction of the needle gives the maximum flow of blood. If the blood spurts out of the cannula, connect it to the instrument. If the blood comes out drop by drop, do not make the connection. It is very important for the success of the transfusion to have a good flow of blood from the donor's cannula before connecting the latter to the instrument.

Insert the Record Syringe and aspirate blood. Turn the stopper and inject the blood. Continue this until the desired amount has been transfused. A nurse sprays ether on the outside of the Record Syringe. In this way only one record syringe is necessary, regardless of the amount of blood to be transfused. For this purpose use a small can of ether, in the top of which only one very small pin-point opening has been made. A hot towel wrapped around the can facilitates the spray

the tissues, the field block will be found of great utility

Field Block This method is well adapted to the major bladder technics such as resections, with deperitonealization as recommended by Voelcker, the diverticulum methods of Lower and others. The transperitoneal resection of Delbru, and the methods in the removal of tumors high up in the bladder as recommended by McCarthy, Scholl and others are readily accomplished under field block. The lower third of the ureter is also readily treated as suggested by Beer, for removal of calculi.

We feel that the deperitonealization methods recently suggested by Voelker represent the greatest achievement made in bladder surgery in many years. Our ability to carry out these technics under local anesthesia presents very great possibilities to the progressive urologists.

Haslinger, Labat and Swartzwold believe that any injections made in the line of incision reduce the vitality of the tissues when placed in contact, with septic bladder contents. While we have not noticed instances of this kind, the experience of these eminent students is deserving of considerable weight. There are three kinds of field block commonly employed, their introduction being largely due to the labors of Hackenbruch, Illyes and Labat. In the one hundred bladder operations listed at the end of this article, all three types have been utilized. The more extensive lesions as best performed under the wide blocks as recommended by Illyes and Labat. Field block is a typical example of conduction anesthesia. In other words, we build a wall of anesthetic fluid which surrounds the nerves in their course and quite thoroughly prevents the passage of impulses.

As can readily be seen, the abdominal wall is quite an ideal place to use this form of anesthesia. We find that much of the innervation occurs from the lateral aspects and is practically in parallel lines. In this connection let it be said that it is well in attempting any local or regional anesthesia to have clearly in ones mind the nerve distribution. This combined with a little patience will prove itself a most valuable adjunct in these procedures.

Type one This method as now practiced is very similar to that originally proposed by Hackenbruch. Its adaption to suprapubic bladder operations is simple and effectual. A superficial wheal is made in the midline of the abdomen an inch and a half or so below the navel. A second wheal is made in the midline about an inch above the symphysis pubis. A lateral wheal is made at the outer border of each rectus muscle and midway between the pubic and subnavel wheals. These punctures now form quite distinctly the points of a rhombus, and it is hence sometimes called the rhombus method. At each wheal a ten cm needle is inserted and thrust directly

FIGURE I
Suprapubic field block. Type 1

downward, injecting as we go until the aponeurosis is perforated. At the point of perforation a few cc of the Neocaine is injected and fanwise injections are then made toward the poles and the central area. Injections are then also made subcutaneously connecting all the points. Upon completion of the above ten cc of fluid is injected through the lower wheal into the space of Retzius.

FIGURE II
Suprapubic field block. Type 2

serve force. Here we have a vitally important factor, which must influence us in the choice of anesthesia. In perhaps no other class of patients will the baneful effects of narcosis be so pronounced as happens at times in maladies of the urinary tract. Having noted the principal indications for the use of local anesthesia, you will naturally say, what are its contraindications?

There are but one or two factors which militate against its use. They are first, the absence of one who is experienced in the use of this technic, second, the speed mania, as local anesthesia is in no wise compatible with haste. It is extremely difficult, in fact, well nigh impossible, except in a few instances, to anesthetize against pulling and tearing. Great care and gentle handling of the tissue will aid greatly in opening the gates of success.

Choice of an Anesthetic

Many drugs have been employed in Bladder Anesthesia. Cocaine is highly toxic, and we will content ourselves with its mere mention. We have found Neocaine most useful and its action is uniform. In considering the drug to be used, heed should be given to the following points:

- 1 The substance must be less toxic than cocaine.
- 2 The agent must not cause irritation or tissue injury.
- 3 It must be soluble in water, and the solution be stable and possible of sterilization on boiling.
- 4 It should be able to penetrate rapidly.

METHOD OF ADMINISTRATION

It has been our custom for some time to employ the excellent syringes and needles designed by Dr. Labat, and Neocaine as the anesthetic agent. There is still much discussion as to the preparation of the anesthetic. As you will remember, Laewen, in his early experiments, found that by the use of sodium bicarbonate an increased diffusion was obtained. Many surgeons of prominence believe that a small amount of suprarenin should be added, in addition to the bicarbonate. Braun, Labat, Illyes, Jones and others are included in this group. On the other hand, Lowsley¹⁴, Meyer¹⁵ and Schmidt¹⁶ hold that suprarenin increases the toxicity.

Our belief, based on a large clinical experience, convinces us that best results are obtained from a freshly prepared one percent solution of Neocaine. Some of our associates believe that better results are obtained with larger amounts of a $\frac{1}{2}$ percent solution.

PREOPERATIVE MEDICATION

Preparation for anesthesia is essentially that of other urologic procedures. No preliminary narcotization in the form of morphia, scopolamin or other sedative drug is employed, except in the

highly nervous type of patient. This class, however, is not well adapted to local anesthesia.

Forty-eight hours before operation, the patient is given thirty grains of sodium bicarb. If the gastro-intestinal tract is disturbed he is given a five percent solution of the drug by rectum. Twenty-four hours before operation, the patient receives a purgative and he is allowed to have as peaceful a night as possible before operation. If the renal function is found to be not good, the operation is postponed.

ANESTHETIC METHODS

In surgery of the bladder we may apply our anesthesia in the form of

- 1 Terminal or infiltration anesthesia
- 2 Field block
- 3 Sacral anesthesia, usually combined with one of the former
- 4 Spinal anesthesia

Close observation of many cases has convinced us that it is to the best interest of the patient to have our infiltrations as far as possible from the large nerve centers. With this idea we have endeavored to utilize as far as practicable the terminal and field block methods. Spinal anesthesia is extensively used unilaterally by Chute¹⁷, Babcock¹⁸, Rytina¹⁹, Tolson and others with excellent results. We have, however, not been so fortunate, nor have our associates, in the avoidance of unpleasant incidents in connection with spinal anesthesia.

OPERATIVE PROCEDURES

In view of the length of this program, we shall eliminate the technique of cystoscopy and intravesical manipulations and consider at once its major procedures.

SUPRAPUBIC CYSTOTOMY

In practically every operation involving an opening of the bladder by the suprapubic route, we resort to the use of local anesthesia. In experienced hands the lack of postoperative shock and the absence of any irritating effects on the urinary apparatus, particularly the kidney, is sufficient justification for its use. We employ several forms of local anesthesia, depending largely on the nature of the operation, as follows:

Infiltration anesthesia may be utilized by means of the layer by layer method, or by those technics recommended by Farr. For the location of the incision either the middle line or an incision over the rectum may be employed. In view of the tendency to wound hernia in elderly men, we favor the separation of the rectus muscle. Single infiltration is applicable to single cystotomies as in a first stage prostatectomy, the removal of stone, etc., without complications. Where one finds it necessary to resort to more extensive dissections, with much retraction of

BLADDER OPERATIONS UNDER LOCAL ANESTHESIA

No of Cases	Average Age	Diagnosis	Type of Operation	Anesthesia	Post Oper Re-action	Result of Anesthesia
14	49	Stone in Bladder	Lithopaxy	Sacral	None	Excellent
9	52	Stone in Bladder	Suprapubic Cystotomy	Suprapubic field block	None	Excellent
2	66	Stone in Bladder	Perineal Cystotomy	Sacral Anesthesia	None	Excellent
4	38	Stricture of Urethra	Retrograde Catheterisation	Suprapubic field block and Sacral	None	Excellent
4	42	Tumor Bladder Dome	Deperitonealisation resection	Suprapubic field block and Sacral	None	Two cases were sensitive on stripping Inhalations
3	54	Tumor Bladder Post Wall	Transperitoneal resection	Suprapubic field block and Sacral	None	Complete anesthesia in 2 cases, third required inhalation
8	40	Tumor of Bladder Base	Extra Peritoneal removal	Suprapubic block and Sacral	None	Six complete anesthetics, 2 inhalations required
3	32	Diverticulum	1 Transvesical } Resection	Suprapubic field block and Sacral	None	Excellent
7	41	Ureterotomy	2 Extravesical } Lower ureter and beer Type Incision	Suprapubic field block	None	Slight pain in exposing ureter in 4 Small amount of ether
12	58	Bladder Carcinoma	Suprapubic cystotomy with radium	Suprapubic field block	None	Excellent
34	39	Varied Bladder Lesions	Cystoscopic manipulations	Sacral Anesthesia	None	Incomplete anesthesia in 3

Type two This represents the author's modification of the Illyes block. Briefly this is as follows. Eight wheals are made in the corium. The first one and a half inches below the umbilicus in the median line. A second just above the pubic symphysis. Three wheals are then made at the outer border of each rectus muscle, one close to the pubic arch, one just below the umbilical level and a third midway between the two. At each of these points we penetrate the aporemosis and inject a few cc of the anesthetic fluid. Fanwise injections are then made submuscularly and subcutaneously, connecting the points of puncture. Through the lateral wheals injections are also made up and down the rectus border. Through the upper midline wheal injections are made downward and laterally. Through the lower midline wheal the space of Retzius is injected with about ten cc of one percent Neocaine.

Type three The introduction of this particular type is largely due to the studies of Labat. It is both simple and effectual. It is of very great value in practically every operation on the urinary bladder by the suprapubic route. It has been our custom to carry out this procedure with slight modifications essentially as follows. Wheals are made just above each pubic spine at the outer rectus border. Another wheal is placed in the same just below the navel area, while the third is made midway between the two. Subcutaneous and submuscular injections are made fanwise all along the lateral border of the rectus as described in the type block two. The space of Retzius is also injected in the same manner. We have utilized this technic in a large number of operations performed by various surgeons. Some of the cases were rather extensive resections, involving the vault of the bladder, and it has proved most satisfactory. In all operative procedures on the bladder other than a single cystotomy, it is advis-

FIGURE III
Suprapubic field block. Type 3

able to precede the field block with sacral anesthesia. This as a rule will with proper care and technic give us a painless operative field. One, however, at times sees a case in which there is a certain amount of bladder sensation in spite of the utmost care. This is particularly true where we are attacking the peritoneal surfaces, or its immediate vicinity. We have so frequently discussed the sacral technics that we shall omit them here. The appended table shows the results of regional anesthesia in 100 bladder operations covering a period of a little over three years.

tibias Still unable to touch heels on floor, but can stand on toes There is less tenderness over all muscles

In one week the tenderness in legs and forearms had disappeared, but child was very weak Eleven days after admission the eosinophiles were 56% and on March 19 were 71% The boy made a slow but steady improvement and left the hospital on March 31, 1924 On May 2, 1924, he complained of some pain in his right leg Leucocytes, 8,300 Eosinophiles, 15% On July 28, 1924, his blood showed Erythrocytes 4,480,000, Leucocytes 7,450, Hemoglobin 69%, Eosinophiles 7%

R D Sister of F D Age 8 years Complained of pain in forearms and calves of legs Unable to place heels on floor Eyes have been quite prominent for five days

Physical Examination

Well nourished and developed young girl, rather pale but does not seem to be having pain

Head Symmetrical Scalp Normal

Eyes Pupils equal, regular and react normally to light and accommodation Conjunctivae negative Eyeball somewhat prominent and there is slight edema about the eyes

Nose negative Mouth Teeth in fair condition, Tongue clear, Throat negative Neck No palpable glands, no pulsations

Chest Well developed Respiratory excursion good Breath sounds normal No rales heard Heart sounds regular No murmurs detected

Extremities Forearms both tender and muscles seem spastic, cannot fully extend forearms Veins of arms very prominent

Legs Calves of legs very tender and slightly oedemations When child stands up she stands on her toes and cannot put heels on the floor Veins prominent

Reflexes Knee jerks absent

The urine was negative for albumen and sugar but contained many white blood cells The number of cells in the urine became less during the stay in the hospital

The Wasserman reaction was negative with plain alcoholic antigen but 4 plus with the cholesterinized antigen The State Health Bureau found the Wasserman negative by both antigens The spinal fluid also gave a negative Wasserman

Trichinella Spiralis found in centrifuged spinal fluid Blood count Erythrocytes, 3,410,000, Leucocytes, 12,300

Differential count Neutrophils 60%, Lymphocytes 35%, Basophiles 1%, Myeloid cells 4%

The subsequent course in the hospital was much the same as that of the brother On the eleventh day it was also found that the

eosinophiles had increased to 50%, the white count being, 20,000

She was discharged on the 33rd day to report to the Out Patient Department Was seen again on July 25th At that time there was no tenderness The heart showed a faint systolic murmur at the apex but was regular in rhythm and rate Hair had fallen out to some extent

At that date the red cells were 5,800,000, Leucocytes 5,500, hemoglobin 65%, Eosinophiles 7%

The mother was admitted to the hospital and although the parasites were not found we were certain that she had also been infected with trichinosis

The history of the sister that died gave the same group of symptoms and it is safe to assume that she also had the disease

One other child had swelling about the eyes but no history of muscle tenderness There is no doubt that four in this family, one adult and three children had trichinosis

It was also learned that the whole family had eaten home made sausages previous to the onset of the symptoms The pork had been purchased at a local market The exact time of the purchase or when the sausage was made could not be learned Of course they were of the opinion that it had been sufficiently cooked

It is interesting to know that in January, 1924, five positive cases and one suspicious case of trichinosis were reported to the Rochester Health Bureau Three of these cases died They were all infected from the same source

Further facts regarding these cases are not available and they are reported for record only

In September, 1923, another case was discovered, the diagnosis being made on the medical service at the General Hospital by finding that trichinella in the spinal fluid

This patient was a female aged 48 years The differential count showed 62% of eosinophiles Recovery was uneventful

ETIOLOGY

The parasite, *Trichinella Spiralis*, was discovered in 1835 by Paget, who was then a medical student working in a London dissecting room It was not until 1860 that it was showed by Zenker to be the cause of the disease, trichinosis

Some of the facts regarding this parasite are well worth considering It is practically always introduced into the human body by infected pork although one series reported in this country was due to infected beef The parasite is found in rats, hogs, dogs, mice, rabbits and occasionally in other lower animals It is by the rat and the hog that the disease is kept in existence From 50 to 100%

TRICHINOSIS IN CHILDREN *

By JOHN AIKMAN, M.D.,

ROCHESTER, N. Y.

WHILE trichinosis is a rare disease in this country recent experiences in this state have demonstrated that one must always be on the outlook for the condition, especially among foreigners who are in the habit of eating poorly cooked pork.

Owing to the fact that small children do not, as a rule, eat pork, trichinosis is rarely found in childhood. For the same reason very little regarding the condition is to be found in text books on Pediatrics. However, three of the four cases to be reported were children, which shows that we must be on the outlook for the disease, especially among foreign children who may at an early age eat the same food as the adult members of the family.

Since so little is to be found in works on Pediatrics regarding the condition, it would seem worth while to give a general description of this interesting disease while reporting this group of cases.

Two of the four cases here reported are interesting because of the absence of eosinophilia and because the diagnosis was proved by finding the trichinella in the spinal fluid. As eosinophilia probably leads to the diagnosis in the majority of cases it is considered by many to be a constant factor. These cases prove that a low eosinophile count does not rule out the disease in a suspected case. The diagnosis was probably missed in an earlier case in this group because too much dependence was placed on the blood picture.

The cases here reported were first seen by the writer on February 27, 1924. The mother and three children had been taken ill about 3½ weeks before. The family were Italians and gave a very unsatisfactory history. One of the children, age 10 years, had died that morning at another hospital and had complained of general pains and symptoms similar to those of the other children. It was learned later that this child had a low eosinophile count and was thought to have died of rheumatism. One other child had been slightly ill, but the rest of the family were well. Severe pains in the forearms and calves of the legs had been present for several days. The children could stand and walk on their toes, but could not place their heels on the floor. They denied having had any intestinal symptoms.

The mother and one of the children had several days before shown swelling about the eyes. They denied having eaten raw meat. No history of previous diseases could be obtained in any of cases.

Scant as the history was it strongly suggested

that all had been made ill by the same agent, probably an unusually infectious disease.

A tentative diagnosis of Trichinosis was made and the children were transferred to the General Hospital.

Physical Examination

F. D. Boy, age 12 years. Fairly well nourished and developed. Pasty in color. Is dull and apathetic. Does not respond readily to questions.

Head Symmetrical, no injuries. Scalp negative.

Eyes Pupils equal and regular, appear slightly dilated but react to light and accommodation. The eyeballs appear a little prominent and the lids are discolored. Conjunctivae clear.

Nose No deformity, no obstruction, no discharge.

Mouth Teeth in fair condition. Mucous membranes slightly pale. Tongue, coated.

Throat Negative. Neck Few small glands palpable on both sides, no abnormal pulsations. No tenderness.

Chest Well developed.

Lungs Respiratory excursion good, equal on both sides. Percussion normal. Breath and voice sounds normal. No rales heard.

Heart Rate 124, regular, no murmurs detected.

Abdomen Slightly distended and shows moderate generalized tenderness. No masses palpated.

Extremities Arms Some spasm of muscles of forearm, cannot be fully extended. General tenderness of forearm less in upper arm. Veins are markedly distended. Legs Some oedema of lower leg. Calves very tender. Legs cannot be extended. Feet, held in extension, cannot be flexed on ankle. Back held rigidly and patient cannot straighten up. Cannot sit up. Lower thoracic and lumbar regions quite oedematous.

The urine contained a few white blood cells, but was otherwise negative. The blood showed 4,210,000 erythrocytes per c. mm. Leucocytes, 6,100, Hemoglobin, 65% differential count. Neutrophils, 69% Lymphocytes, 30% Eosinophiles, 1% Spinal fluid Clear, colorless, ± Pandy 6 Lymphocytes per c. m. Trichinella spiralis larva found. Wasserman reaction of blood negative to both antigens. Spinal fluid also negative to both antigens.

X-Ray Muscles of leg. No areas of calcification.

Feb. 29 Veins of arms while not distended are very much more prominent than in normal child of this age. Arms and legs have a full, tense feeling and legs show slight edema over

*Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse May 13 1925

val hemorrhages may occur as well as nose bleed

Bronchitis and dyspnea may occur. The patient is dull and may even be delirious. The tendon reflexes are usually lost. The urine shows albumen, hyaline and finely granular casts.

(3) Stage of Encystment

At the end of about four weeks improvement begins. The temperature returns to normal and the muscles become less swollen and tender. The patient is as a rule emaciated and anaemic and the facial edema remains for some time. A milium eruption and pruritis may occur. Convalescence is long drawn out and weakness persists for several months.

Children as a rule run a milder course which Van Cott and Lintz attribute to the fact that they would be likely to eat a smaller amount of pork. The amount taken being considered the most important factor.

DIAGNOSIS

When other cases have recently occurred in a locality the diagnosis is fairly easy. Usually there are several cases in the same family group. The similarity of the symptoms in several cases should at once point to an infectious disease. The fever is frequently mistaken for typhoid and the pain for rheumatism. The pain is however more marked in the muscles and only acute neuritis gives as severe pain on pressure. If a history of eating poorly cooked meat can be obtained one is relatively certain of the diagnosis.

We have been taught to expect a very high eosinophilia but this may be absent. Usually the eosinophilia persists for months. Block and others have called attention to the low eosinophile count that may be found in the acute stage of the disease, this count increasing during convalescence. The disease should not be excluded by a low eosinophile count but a high eosinophile count points strongly toward trichinosis. Opie claims that the more severe the infection the lower we may find the eosinophiles.

The leucocytes run from 25,000 to 30,000 per cubic millimeter.

The parasites may be found in the stools but are more often missed. The embryos have been found in the blood stream.

In 1913 Van Cott and Lintz first found trichinae in the cerebro spinal fluid 21 days after the infection had occurred. Since that time a number of men have made the same findings and it has become a very valuable method of detecting the presence of the disease, especially in the period of dissemination.

While some are doubtful of the value of this method of making the diagnosis it has proved of great value to us especially in the

presence of a low eosinophile count. No one method need be used to the exclusion of all others and cerebro spinal fluid examination is of great assistance in some cases. It has the advantage of being more easily and quickly done than the examination of a piece of muscle. After the fifth week the encysted embryos can be found in the muscle.

PROPHYLAXIS

It would at once seem that proper meat inspection would prevent the disease but this cannot be depended upon to rule out the presence of the parasite. The examination must be microscopic. The hog is a large animal and the portion containing the worms may easily be missed.

The disease would be eliminated if people would stop eating raw or poorly cooked meat. Wide publicity of the dangers of eating poorly cooked food should be disseminated and prepared foods such as sausage should be kept from sale unless properly cooked. It is not necessary here to give the figures of investigations as to the time and temperature required for pieces of any certain size, but such investigations have been carried out by our Government, and the results are available. It is obvious that it takes very much longer for heat to penetrate the center of a large mass of meat and destroy the parasite than it would take for a slice of ham.

When cases occur, the pork, usually sausage, should be traced back to its original source. It is very difficult to trace the source of infected meat, as the store-keepers buy from different sources at different times, and are unable to tell from whom the meat was originally purchased. By the time the infection is discovered most of the details of the purchase have been forgotten. Only by keeping a record of the sale of pork in the public market and of retail sales by store-keepers could these cases be traced back.

PROGNOSIS

The severity of the disease depends on the number of living worms taken. The mortality is less in children, probably because they eat less of the pork than do the adults. Early vomiting and diarrhoea often reduce the intensity of the infection.

In Ransom's tabulation of 320 cases reported in the United States from 1909-1914 the mortality was 6 per cent. All the reported cases in the United States, 1550 in number, had a mortality of 16 per cent. This high rate is probably due to the failure to report mild cases. In Germany the mortality is given as 5 per cent. While trichinosis has a fairly high death rate, it also causes long debility and economic loss.

of rats about slaughter houses have been found infected. This is due to the fact that the rats eat trichinous pork. If hogs are kept near such slaughter houses they in turn eat the rats or may eat scraps of pork and so the disease is kept alive until this circle is broken. Man becomes a host only by accident and does not pass the disease on to others.

The *trichinella spiralis* is from 1 m m to 3 m m in length. In the adult and sexual condition it lives in the intestine of its host. The female gives birth to at least 1,000 to 1,500 young.

When trichinous meat is eaten the cyst holding the parasite is digested and the worm is liberated. It has been estimated that infested pork may harbor 85,000 encysted worms to an ounce.

The fertilized females burrow into the mucosa of the intestine and discharge the numerous embryos into the lymph spaces of the mucosa and submucosa. It is then probably that they travel with the lymph to the thoracic duct and to the right heart. The embryos are smaller than red blood cells and they are easily carried by the general circulation to the striated muscles where they elect to remain and penetrate into or between the muscle fibers.

In nine or ten days many have reached the muscles where they grow rapidly. In one month the worm begins to encyst which process takes from 8 to 12 weeks. Here they may live from 20 to 30 years. The life activity ends unless the meat is eaten, when this occurs the cycle begins again. The parasite is able to pass both the sexual and asexual stages in the same host.

At least 100,000,000 encysted worms have been estimated to be present in one ounce of muscle in a human subject.

It has been found by microscopic examination that from 1 to 3% of hogs contain the parasite. It is common throughout the world.

The outbreaks in this state have occurred mostly among the foreign population especially those who are in the habit of eating poorly cooked pork usually in the form of sausage. When the sausage is made in the home or in a small market all of the meat is likely to come from one animal and the infection is more concentrated than if the trichinous pork were mixed with good pork. Hence sausage from large establishments is not as apt to give intense infections. Chapin and Pisek call attention to the liability of infection on farms when home cured pork is eaten.

Ranson found 1,558 cases on record in the United States between 1842 and 1914, New York led with 355 cases. It is common in Germany.

Williams making a special search for trichinae found them in 5.34% of 505 post-mortem

examinations in Baltimore, Philadelphia, Detroit and Denver, none of these subjects died of trichinosis.

Some investigators claim that from $\frac{1}{2}$ to 2% of all human bodies contain trichinella. This is based on autopsy figures. Of course such figures would depend on the country, the nationality of the subjects, the general public health and the care with which investigations were carried out. If such figures even approach accuracy it is evident that in only a small number of cases infected with trichinella is the infection severe enough to produce symptoms. Moore states that when a limited number of encysted larvae are eaten only a few embryos enter the muscles and no symptoms are produced.

The capsule protects the worm from salt and antiseptics, but heating trichina to 122° F will kill the parasite in 10 minutes. Exposure to 12° F for 15 days while it did not kill the parasite, rendered the infection less severe.

The adult worms produce their effects in the intestine and the muscular, symptoms are caused by the embryos. The adult worm dies after 6 to 7 weeks and are probably digested as they are rarely found in the stools.

The embryos are most numerous in the muscles having the best blood supply, the diaphragm, intercostal muscles, muscles of the neck, larynx, tongue and eyes. They may even be found in the heart muscles. They may be found practically in any tissue, and can be detected in the pleural and peritoneal cavities. They are numerous in mother's milk but are not found in urine.

They do not complete their development and encystment in anything except striated muscle.

History—As the cases reported do not present the typical symptoms of the disease it will be of advantage to mention the usual findings. The symptoms may be divided according to Whitmore, into 3 stages following the development of the parasite. (1) Stage of Intestinal Infestation. Nausea, vomiting, abdominal pain and diarrhoea may begin a few hours after the meat is eaten. The temperature may rise to 102 to 104. The diarrhoea increases and the stools may contain blood and mucus. Prostration is marked. Pain and stiffness of the muscles and occasionally twitching are noted early. It may be 7 to 9 days before the symptoms develop.

The second stage of dissemination begins by the end of the first week while the embryos are invading the lymph and blood streams. It is marked by edema especially of the face. High temperature with morning remissions. Profuse sweating is present. The severe muscular pains cause flexion and contractures. The muscles are stiff, hard and tender. Even the eye muscles are affected and subconjuncti-

THE NEW YEAR

To the medical profession of New York State we extend a New Year's greeting

Another year, in its beginning, must inspire every one of us with resolves for betterment

Nineteen hundred and twenty-six should be a year of accomplishment. As a profession we should be unified in resolve, strengthening the hands of leadership with no obstructive love of self

We stand primarily for service, and whatever contributes either in scientific improvement or

medical advance is another step forward for the economic welfare of the community

Times are changing, and the practice of medicine is changing likewise. In an age of specialties let us not depart from the basic study of the fundamentals, which are the real meat of medicine. Let us take advantage of every method of relieving human pain, but in no wise be carried away by the wail of the quack and the charlatan.

In addition, let us add to the intelligent study and treatment of disease a pleasing personality, and we will find nineteen hundred and twenty-six a well-rounded year

TREATMENT

If a patient is seen early enough it would be of advantage to wash out the stomach. Cathartics given early help to remove the infection. Thymol may help if given early, and thymol in sterile olive oil (gr 1 in 1 cc of oil) has been used subcutaneously and intramuscularly by Booth.

Salzer treated 14 cases of trichinosis successfully with convalescent serum.

Generally, however, the treatment is symptomatic.

CONCLUSIONS

Ten cases of trichinosis were found in Rochester from September, 1923, to February, 1924.

It is apt to be found among the Italian population, who are in the habit of eating poorly cooked pork, chiefly as sausage.

The disease may occur among children in Italian families and should always be suspected when symptoms of severe muscular tenderness are present.

The disease cannot be ruled out by a low

eosinophile count, because this may be present during the acute stage.

In many cases the diagnosis may be cleared up by spinal puncture and examination of centrifuged spinal fluid.

ZITZ, FRANK H, New York City, College of Physicians and Surgeons of New York, 1888, Member State Society, Alumni Association Lenox Hill Hospital. Died November 26, 1925.

forms Curative medicine can be practiced by individual doctors with small regard for their confreres or the public generally The practice of preventive and promotive medicine requires organization These forms of medicine can be practiced by doctors in private practice by means of their organized medical societies One of the greatest fields of activity of medical societies is the practice of civic medicine Doctors in private practice are ready and eager to support medical societies through which they can discharge their civic duties Not all doctors are fitted to practice civic medicine, and take the lead in medical societies and other

public health organizations But while a few can always be found to do the work of leadership, the rest can pay the dues by which the work is supported, and can keep themselves informed concerning the work of their medical societies

When departments of health and lay organizations deal with individual doctors, they are sometimes inclined to rate the medical profession low in its interest in public health If they would deal with the representatives of the medical societies, they would find the medical profession active in the support of all phases of public health work

COOPERATION WITH LAY ORGANIZATIONS

The Health Conference held in New York City, November 19th and 20th, under the auspices of the United States Public Health Service, the New York State Department of Health, the New York City Department of Health, the Milbank Memorial Fund, the State Charities Aid Association and the New York Tuberculosis Association was largely attended both by professional and lay persons The conference showed plainly that the adoption of the measures and methods approved by experts in preventive medicine and public health administration raises the standard of health and reduces the amount of sickness in the state It was noticeable that no medical organization cooperated with the six health bodies Why this was so should arouse the interest of physicians Did they as an organization decline, or were they not given the chance?

Since health organizations must always look to physicians for knowledge and guidance as to the nature of disease and the proper method of overcoming it, and also for the methods of promoting public health, it would seem eminently fitting that the great organization of the New York State Medical Society with its more than ten thousand members should have been a cooperating member in a health conference projected on so splendid a scale.

Organized medicine in New York State accepts the duty and responsibility of supplying

methods and guidance in the promotion of public health, and would be glad to join officially with other health organizations in bringing this knowledge to the general public

The new activity in the State Medical Society, that of Graduate Medical Education—has for its direct object the post graduate education of every physician, and the promotion of public health The success of this campaign will go far to solve the public health problem It is admittedly the best prospect today for service to the practitioners of medicine, and also to the general public

All welfare and health organizations are of great value in making effective the distribution of real medical knowledge and discoveries and the application of methods to solve the health problems There is work enough and room enough and glory enough for all

The State Medical Society welcomes any opportunity to make its knowledge of disease and prevention effective just as soon as the new discoveries and new methods are proven true and correct, and useful in educating the public as to how it may obtain its benefits It is proper to arouse public interest and create enthusiasm in any reasonable way until attention is fixed, but after the real knowledge of disease is ascertained, the method of prevention and the promotion of public health must follow scientific and accepted lines As Dr

FIELDS OF MEDICAL WORK

Physicians are not the only persons who are engaged in health work. The practice of medicine in its broadest sense is in the hands of three groups of persons: 1, the medical profession, 2, departments of health, and 3, unofficial organizations of laymen. The fields of these three groups overlap, and misunderstandings between them often occur. If each group keeps clearly in mind its own proper field of activity, harmony and cooperation will be assured.

There are three general divisions of the practice of medicine: 1, the curative, 2, the preventive, and 3, the promotive or the promotion of health and vigor.

The divisions of practice covered by each of the three groups of health workers is shown in the accompanying table.

The practice of curative medicine—that is, the treatment of sick people—belongs exclusively to physicians. Boards of health enter the field to some extent with the consent and solicitation of doctors, but lay organizations have practically no place in curative medicine, except indirectly in such activities as the management of the business side of hospitals, public health nursing associations, and similar organizations. If this principle is kept in mind by the nurses and social workers and even the doctors employed by lay organizations, the greatest source of friction and misunderstanding will be removed.

The practice of preventive medicine is the peculiar function of departments of health. The prevention of diseases is principally a community problem, and therefore it is properly done by public officials.

A physician in private practice also has a duty in preventive medicine—that of protecting the individuals of the families in which he is the family doctor. Many physicians consider that their duty ends here. If the

family medical advisor treats the sick and takes active measures to protect the well members of his families, he does a great public health work, but in order to do this, it is necessary that he cooperate heartily with departments of health and, also to a considerable extent, with lay organizations.

However, a large proportion of the people—probably one-third—are unable to avail themselves of all necessary preventive measures because of financial, educational, or other reasons. Even departments of health are unable to reach some people. To assist and educate these people in utilizing the benefits of preventive medicine is the peculiar field of lay organizations, such as charitable societies, tuberculosis associations, and visiting nurse organizations. Hospitals, housing, poverty, and crime all have an extensive influence on health, and the management of these conditions belongs to lay organizations, and to officials of other divisions of government besides the health department. This work consists largely in educating the people and in demonstrating the methods and values of the newer lines of activity, with the expectation that departments of health and other governmental agencies will assume the work.

The health work of lay organizations consists in a great deal more than passively guarding against threatened epidemics; to a much greater degree it consists in actively promoting such a degree of health and strength that people not merely escape the hades of sickness, but that they also attain a heaven of vigor and efficiency. This is the object of the great movement to promote the practice of periodic health examinations by physicians in private practice.

Physicians generally realize their civic duty to engage in the practice of preventive and promotive medicine, as well as the curative

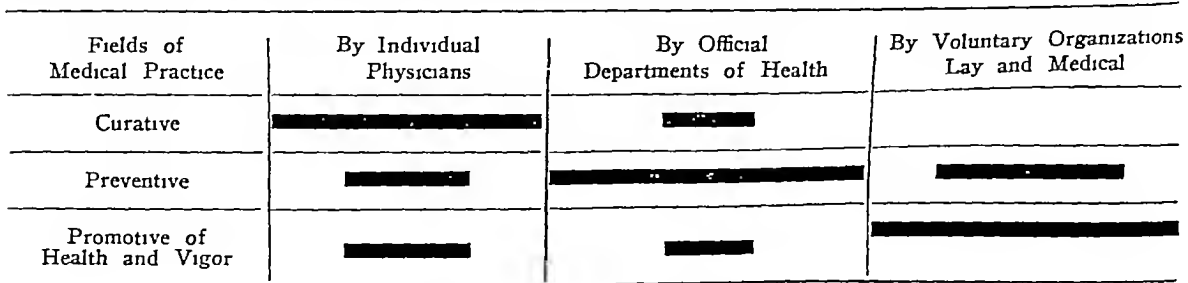

DIAGRAM OF HEALTH ACTIVITIES

The lengths of the bars represent the relative proportion of effort put forth by the three great groups of health workers in the three great fields of health work.

MEDICAL PROGRESS

Treatment of Paresis by Malaria Inoculations—Schulze, head of the Dalldorf Insane Asylum, Berlin, reports his experience with the Wagner-Jauregg method of malaria inoculation in the treatment of general paralysis of the insane. Writing in the *Deutscher medizinische Wochenschrift* for November 6, 1925, he states that he began the use of the malaria virus in 1922, following the favorable reports from Wagner-Jauregg of Vienna. He has now inoculated 450 paretics with malaria. Unlike his predecessors in this field, he has refrained from making use of salvarsan or any specific drug in the after-care, believing it wisest to try out the malaria treatment alone. The number of cases available for statistics was 215 and the results were classed in four groups. Group I comprised only arrests or recoveries, and here belonged 78 patients. Some of the remissions would doubtless have come about without the treatment, but the interval of quiescence averaged much longer than in spontaneous remissions. Group II comprised improvements and numbered 29, so that the total positive results came to 107 or almost exactly half. Group III comprised all living who did not benefit by the treatment, most of the patients showing the usual progress of the disease. The number under this head was 65. The fourth group was made up entirely of patients who had succumbed to the disease since beginning the treatment. In none of these fatal cases, however, did the malaria inoculation appear to have caused the death. According to the conditions of the treatment it is allowable to give the patient quinine as usual. Inoculation was performed with a strain of tertian malaria injected under the skin or intravenously. Concerning the nature of this cure nothing is known. We only know that in the brain of a dead parietic who has received the treatment the iron reaction is less marked than in an untreated case.

The figures of some of the other observers are equally favorable. Gerstmann, collecting the records of Jauregg's own clinic, reports 112 patients who had a resumption of working power with complete remission of the psychic symptoms out of a total of 294 cases in which the data were complete. Of the remainder 90 were able to work, but were not fully restored mentally. The reports from English observers, while on the whole rather encouraging, are much less convincing. In four series of cases published in *English journals* in 1923 and 1924, there were reports of 75 cases, in 13 of which marked improvement, one might almost say cure, was noted, while some benefit was apparent in 21, in the remaining 41 little or no change

occurred. In most of the reports, from both Austro-German and other sources, mention is made of an occasional death from the induced tertian fever. The behavior of the serum reactions in the cases of remission of the clinical symptoms was not uniform. In some the Wassermann and other reactions remained unaltered, in others the blood Wassermann disappeared early, but the cerebrospinal Wassermann persisted for several years, and in some cases indefinitely. The cerebrospinal lymphocytosis sometimes persisted after the blood Wassermann had definitely disappeared.

The Cause of Convulsions in Whooping-Cough—Most writers of pediatric text-books attribute the nervous complications of whooping-cough to asphyxia, central edema or congestion, brain injury from hemorrhage, encephalitis or meningitis. Chapin, for example, attributes them to cerebral congestion or capillary intracerebral hemorrhage. But the outstanding symptom of all these conditions is convulsions, and the rarity with which definite pathological lesions are found post mortem is in striking contrast to the frequency with which convulsions occur. As a matter of fact, says Grover F. Powers, in an article in the *American Journal of Diseases of Children*, November, 1925, xxx, 11, it is quite probable that the existence of convulsions in whooping-cough has frequently been the principal basis upon which a diagnosis of cerebral hemorrhage, encephalitis or other lesion has been set up. The finding of electrical hyperirritability of the nerves and a reduced calcium concentration of the blood serum in several infants with whooping-cough and convulsions leads the author to suggest that infantile tetany, and not anatomical injuries or an unknown toxin, is often the cause of convulsions in whooping-cough. The wide recognition of this fact is important because the convulsions of pertussis, in which death not infrequently occurs, may be amenable to treatment when the patient has tetany. A fact that lends support to the view that tetany is a cause of convulsions in pertussis is that this complication is most frequently observed in rachitic infants. This was true of all the cases studied by Powers. It would thus seem that it is important that the calcium concentration of the blood and the electrical reactions of all infants with whooping-cough should be determined, if possible, and therapeutics may then be guided by the evidence for or against the existence of latent tetany. In the event that this determination cannot be made, the writer suggests that calcium chloride should always be administered to young children who have whooping-cough.

Welch says "Mere repetitions of claims, mere reiteration that certain diseases can be prevented, is not sufficient. To bring a knowledge of preventive medicine to the public is one of the duties and responsibilities of organized medicine. Better team work on the part of medical societies and health agencies in presenting the great discoveries in medical science and making their distribution more effective would promote public health and preventive medicine."

When Dr. Welch said that we know how to do a lot of things which we don't do or do on a wretchedly small scale, and that most of the great discoveries in preventive medicine were not fully applied, he stated a fact. In all true advance in health promotion conservatism is necessary in the interest of truth and also in gaining the confidence and cooperation of the public in their adoption of methods that to

them are revolutionary. It is necessary to go slow enough to educate as we go.

There is no group of men who can be of as much use in preventive methods as practitioners of medicine in their daily work as medical men. No other group can so effectively distribute medical facts. Organized medicine will take a prominent part in the distribution machinery. Physicians should be welcomed as co-workers and councillors by every health organization.

There was a resolution adopted by the New York State Committee on Tuberculosis and Public Health of the State Charities Aid Association, inviting the President of the State Medical Society to become a member of the Executive Committee. This is evidence of the desire of a lay body to cooperate with organized medicine.

LOOKING BACKWARD A QUARTER CENTURY AGO

Twenty-five years ago the *NEW YORK STATE JOURNAL OF MEDICINE* first appeared as the organ of the New York State Medical Association. The first article begins:

"With the present issue the New York State Medical Association begins the monthly publication of a Journal which will take the place of its annual volume of Transactions. The example should be followed by every State Medical Association in this country. Every member of a live organization, whether lay or medical, should be in close touch with the aims and purposes of that body. He should feel himself a vital part of it, should work for its interests, should raise his voice when occasion demands for all that is best and progressive. The members of the New York State Medical Association now have this opportunity placed before them."

"From month to month will appear the scientific papers presented at the Annual Meetings of the Association. The department of Association Notes will contain news items, letters and correspondence, notices of removals and deaths, and an occasional short sermon, perhaps, on the needs of the Association or of the profession at large throughout the State."

The new publication was in charge of a committee on publication consisting of James Hawley Burtenshaw, Wisner R. Townsend, Stephen Smith, J. W. S. Gouley and Frederick Holme Wiggan, all of New York City.

The first issue contained thirteen pages, of which six were devoted to news and six to scientific articles, and only three to advertisements. Still it contained the main features of the Journal as it now exists.

TWENTY YEARS AGO

The first article of the *NEW YORK STATE JOURNAL OF MEDICINE* of January, 1906, begins as follows:

"At a special term of the Supreme Court, held at Rochester, December 9, 1905, Judge J. M. Davey signed the order consolidating the Medical Society of the State of New York and The New York State Medical Association, according to the terms of the Agreement prepared by the Joint Committee of Conference, and approved by both organizations at their annual meetings in 1905."

"The New York State Journal of Medicine

will be continued as the official organ of the Society. Every endeavor will be made to make it attractive, interesting and worthy of the profession of the Empire State. It will publish the Transactions of the State Society, news items of interest, book reviews, and valuable original articles. Its aim will be to promote the best interests of the profession, to advance the science of medicine, to elevate the standard of medical advertising, and to assist in every way in upholding the honor and dignity of the Medical Society of the State of New York."

nucleate cells should not be over 4 to 6% —
Muenchener med Wochenschrift, Oct 9, 1925

Diagnostic Significance of Phenol in the Blood.—Becher, Litzner and Täglich make a short preliminary contribution on this subject. We know that combined phenol exists in normal blood, and that it may be greatly increased during certain diseases, while at the same time free phenol begins to appear, and its presence may be recognized by Millon's reaction. Hitherto we had known that phenol is largely increased in uremia but since it only runs parallel with the urea, retention a positive find adds nothing to our ordinary diagnostic resources. In other diseases it is likely to be different, and among others the authors have found a notable increase of combined phenol with the presence of free phenol in the blood of pernicious anemia. In addition to the possible aid in differential diagnosis, these finds appear to support the enterogenic theory of the causation of this affection. Unfortunately the recognition of phenol cannot be brought into the compass of micro-methods, for at least 100 cc of blood are requisite for the Millon test —
Münchener med Wochenschrift, Oct 2, 1925

The Value of Venesection in the Treatment of the Decompensated Heart—To the student of the history of medicine there is no more striking example of the see-saw of therapeutic practice than that illustrated by the fall from favor of venesection. At the beginning of the 19th century it was the panacea for all the ills of mankind, and when the practitioner did not know what else to do he bled the patient copiously and frequently. At the beginning of the 20th century the man whose patient died after a venesection would probably have faced a suit for malpractice. Nowadays blood-letting is regaining favor, but even yet the one who resorts to it often feels that he is called upon to justify his action. There can be no question, however, that in certain conditions, such as local congestion of some vital organ, heart disease with broken compensation and some toxemic states, the drawing of blood may avert an immediate fatality.

Burgess Gordon in an article in the *American Journal of Medical Sciences* for November, 1925 reports a number of cases in which venesection effected a marked change for the better in the decompensated cardiac patient. The roentgenographic examination of a series of dilated hearts in patients with failing circulation showed a diminution in the size of the organ immediately after venesection. When this occurred, there was a corresponding improvement in the condition of the patient, the myocardium regaining its strength in a measure, with the result that all the organs were more equally and more fully supplied with blood and so better enabled to perform their functions in an approximately normal manner.

A survey of the hospital records showed that numerous patients, bled as an emergency measure after other therapeutic measures, such as drugs, had failed, possibly because of their delayed action, responded favorably to venesection. This experience offers further proof that venesection has a place in improving the action of the decompensated heart and, temporarily at least, in removing the signs and symptoms of cardiac failure.

Total Gastrectomy for Linitis Plastica—Mont B. Reid reports in *Surgery, Gynecology and Obstetrics*, November, 1925, xli, 5, a case of successful total gastrectomy in a woman 51 years of age, which is interesting on account of its rarity. The case was one of linitis plastica in which the stomach was so nearly reduced to a small hard fibrous tube that it was evidently impossible to give relief either by gastroenterostomy or partial resection of the stomach. The entire stomach was removed with little difficulty, but restoration of the continuity of the alimentary tract was quite difficult because of the depth of the wound and the absence of serous covering on the posterior wall of the esophagus. Continuity was restored, however, by end-to-end anastomosis between the distal end of the divided jejunum and the esophagus. Both the esophagojejunal and the jejunojejunal anastomoses were made with the interrupted Halsted mattress sutures of silk. The blind end of the duodenum was inverted by similar sutures. The writer points out that there have been reported in the literature only about 50 cases in which complete gastrectomy has been attempted. Patterson found that 17 per cent of those who recovered from the operation of total gastrectomy were alive and well five years later. The operative mortality was found by Frazier to be 33 per cent. These statistics make the operation of gastrectomy feasible and indicated in properly selected cases.

Management of Head Injuries—Writing in the *Lancet*, of November 7, 1925, ccix, 5332, Wilfred Trotter calls attention to the frequency and importance of minor injuries to the brain which are so often overlooked or ignored after the gross external head lesions have healed. The more severe injuries have long attracted the attention of the surgeon and the indications for operation are fairly well defined. But the nonoperative and, so to say, physiological methods of treatment are of great value and deserving of more attention than they usually receive. Surgical treatment, Trotter says, should be advised when at the end of the first week serious mental changes (profound drowsiness and inertia, delirium or mania) are present and seem to be about stationary. In a few severe cases operation may be called for at an earlier date, but generally the choice of time is not a matter of

complicated by convulsions. As a further precaution, in order to insure the assimilation of the calcium, the simultaneous exhibition of parathyroid extract may be suggested. There is usually calcium enough in the food, but the difficulty in rickets is its nonabsorption.

Treatment of Furunculosis — Busche and Langer of the Rudolf Virchow Hospital, Berlin, consider this subject exhaustively, as to both the underlying condition and individual lesions. The number of local and internal remedies suggested from time to time is a confirmation of the fact that there is no typical management. Not only most of the antiseptics, but every form of vehicle, minor surgical procedure, and physical remedy seems to have had advocates. The authors are apparently testing vaccines and various forms of non-specific protein injections, but they are partial to sulphur in various forms as baths, local applications, injections, by the mouth, etc. In this connection they mention Bier's advocacy of low potencies of sulphur as used by homeopaths. The authors believe this is going too far, for we have no scientific theory to support it. At the same time they suggest that mild remedies should have a fair chance, and that the drastic intravenous and intramuscular injections are justly unpopular with patients. If we wish to use medicines in attenuated doses they suggest the use of thallium, for which there is a scientific justification. Quite a number of metals are known to exert an oligodynamic action on living matter and the smallest ionized quantity of thallium is found to possess antibacterial properties. Insulin also is believed to possess some power even over non-diabetic furunculosis — *Medizinische Klinik*, November 6, 1925.

Caramelized (Anhydrous) Sugars in Diabetes — According to Nonnenbach the discovery in 1914 that caramel can replace glucose in ordinary diets, and in diabetics can be utilized without increasing the hyperglycemia is hardly less important than that of insulin. Following this idea, the water was split off from the molecule of other edible sugars and a new series of products, which like caramel could be utilized as carbohydrate in diabetic diets, was obtained. This series has received the name of glucosans, and among the members levo-glucosan was first found to be well tolerated and to cut the acidosis of diabetes in half. The next to be tested with positive results was alpha-glucosan, and third in order tetro-glucosan. The author announces that he has succeeded by splitting off from ordinary saccharose a certain amount of its intramolecular water, in obtaining a glucosan which he has named saccharosan, and which is apparently the same as mellitose, although this term has already been applied to a trisaccharide. He has tested saccharosan on normal and dia-

betic subjects, and finds that in the former it can be substituted for glucose while by the latter it is very well tolerated — *Muenchener medizinische Wochenschrift*, October 23, 1925.

Roentgen Studies of the Gall-Bladder (Contrast Filling Method) — Eisler and Nyiri have been studying the Graham and Cole American method of roentgenography on 75 patients. In all but five the sodium-thalein salt was given by the mouth. The general impression was of course favorable and the plates shown illustrate very clearly the differences in the shadows of normal and diseased gall-bladders. In summing up, however, the authors are extremely conservative. They cite the case of contrast filling of the stomach and intestine which is a more simple procedure, yet some years were required to develop a suitable routine technique. It will be the same, they think, with the Graham-Cole method. First of all we must solve the technical problems. Secondly, we must obtain the correct idea of a normal gall-bladder. But once this mastery has been obtained, they concede that great things may be expected, especially in the comparatively uncultivated field of the functional behavior of the organ — *Wiener klinische Wochenschrift*, Oct. 15, 1925.

Schilling's Hemograms in the Diagnosis of Abdominal Disease — John refers to a little monograph which appeared in 1924 in which the subject of diagnosis and prognosis by blood counts is intensively treated. In the diagnosis of acute abdominal disease we sometimes encounter silent cases, in which the symptoms may be limited to vague pain and soreness. In other words there are no signs in reference to temperature and pulse, no nausea or vomiting, no signs of obstruction. The ordinary white cell count is non-committal. In such cases the differential blood count, when properly interpreted, will sometimes indicate that a serious condition is present. Again there may have been symptoms — symptoms which harmonize well with the differential counts — but they have receded and the patient appears to have nearly recovered without treatment. A further blood count however shows that this supposed improvement is treacherous, and that the original condition is still present. This is well illustrated by a case in which the author makes use of Schilling's terminology. A man of 56, in excellent health, was seized one forenoon with colicky pains, but without other evidence of disease. The count showed segmented-nucleate cells, 62%, red-nucleates, 24%, eosinophiles, 0%, mononuclears, 1% and lymphocytes, 13% — a picture very suggestive of appendicitis. Overnight the patient showed improvement, but as the blood count showed no change for the better, it was thought best to operate. The appendix was of the thickness of the thumb, red, with fibrinous deposit. The normal count of red-

THE GOVERNMENT OF A PROFESSION

IV

In a profession so highly individualistic as medicine, initiative, originality, and the opportunity of personal accomplishment and ambition are essential factors for progress. These activating forces are the main springs to discovery and improved practice. There is no profession so ready to discard the old and take on the new as the medical profession—despite the popular belief to the contrary. But the new must first stand the test of truth applied by the profession through its scientific organizations before it receives professional acceptance. How short-lived is a medical or surgical fallacy because of the application of these principles! How acutely sensitive is the profession to the exploitation of new ideas to the lay public before they have been examined and adjudged sound! Why should this be? Because the lay public have too often been misled and victimized by the pseudo-scientists whose claims are such alloy of truth with the baser elements of fraud and empiricism that only the tests of scientific minds and experience can expose them. The rule which requires, before public exploitation of medical discoveries, a careful and searching test by the profession of the claims has doubtless saved the public many dollars and numerous lives.

But what redress has the profession against the man who today, within the law, defies this custom and masquerades before the public as its great benefactor for his own gain, who eschews professional standing with his brethren for the spotlight of the public's approval, who charges those who question his claims with motives of unworthy jealousy or conservatism? Such a man cares little for the severest judgment any censors can give—of professional excommunication, he makes capital of that and twists the motives prompting it to serve his own ends and prove his claim of professional jealousy.

The profession needs to be given more power to enforce its standards of honor and decency. The profession has always established high principles of conduct, but has failed to provide adequate machinery for the enforcement of those principles upon those unwilling to abide by them. A lay body is quite unable to cope with this problem, as it is one that peculiarly requires the background, the psychology, the standing and the experience of medical men.

For these reasons, among others, the proposed bill of the Medical Society of the State of New York seeks to establish a properly constituted and legally equipped committee that may consider all such grievances and apply adequate remedies.

CLAIMED DEATH AS RESULT OF TONSILLECTOMY

In this action the defendant, a specialist in nose and throat work, was charged with negligence in the performance of a tonsillectomy resulting in the formation of an abscess on the cervical glands and the subsequent death of the patient. The complaint charged that the defendant, as such specialist, on May 2nd was engaged to examine and remove the tonsils of a girl of about sixteen years of age, that the operation was performed at his office on May 12th but that the defendant negligently and carelessly conducted himself in the performance of the operation and in the after-care, that at the time of the operation there was active suppuration in and about the tonsils and the defendant was negligent and careless in performing the operation in the presence of such active suppuration, that there was also pus about the tonsils at the time of the operation, and because of this condition the defendant was careless in

using a local anaesthesia. It was charged that the defendant was further negligent in permitting and instructing that the patient be taken from his office to her home on the day of the operation, that on May 16th he was charged with refusing to call at the home of the patient to attend and treat her, but advised that she be brought to his office, that when brought to his office he found a severe swelling on the left side of her neck and her teeth almost locked due to such swelling and stiffness, that at that time the defendant should have been apprised of the fact that the condition of the patient was serious, requiring prompt attention and care, and that he was negligent in not prescribing the necessary prompt care and treatment. He was also charged with negligence on the 17th and 18th of May in failing to call at the home of the patient, and again on the 19th until the evening, at which time it was claimed that the patient was

great urgency, though once it is decided that intervention is necessary there is no object in delay. In mild contusion-lacerations, left by accidents which at the time seem to have produced no serious effect, the cardinal feature is headache, though there may be less conspicuous elements such as giddiness, slight changes of disposition, and minor mental and physical disabilities. The writer calls this condition "contusion headache." It usually declares itself within a few weeks of the accident and the symptoms are of all grades of severity. The most notable features of the headache are its throbbing and paroxysmal character. Its pathological basis is a bruising of the brain with resultant swelling and pressure. In the treatment of this condition rest in bed is essential. In cases of cerebral contusion, as in other conditions accompanied by intracranial congestion or edema of the brain, there is a certain accumulation of cerebrospinal fluid which tends to contribute to the disturbance of the intracranial tension. This excess may be reduced by lumbar punctures or by the administration of hypertonic saline solution. Lumbar puncture has its chief value as an emergency measure in severe attacks, while hypertonic saline solutions of magnesium sulphate, administered by preference in the form of an enema of 3 ounces of the salt to 6 fluid ounces of normal saline, daily or even twice daily, is said to be capable of producing obvious relief of these milder intracranial pressure symptoms. Manifestly, however, neither of these measures can be carried on indefinitely. A method of exercising a steadily favorable effect on the intracranial tension is a simple one of posture, and this the author has found of surprising value in the relief of headache due to this cause. Rest in bed and rigid enforcement of the propped up position in order to favor the venous outflow from the skull are indispensable for prolonged treatment. In the author's experience they have effected an astonishing diminution in the frequency and severity of attacks of contusion headache.

Clockwork Control of the Carrel-Dakin Treatment—Finding it impossible to obtain a satisfactory method of intermittent irrigation with a siphon automatically discharged by slow dropping of the fluid, Charles W. Cathcart (*British Medical Journal*, November 21, 1925, II, 3386) has invented a device by which the fluid can be discharged from a siphon, at intervals, by clockwork. The clockwork and electric mechanism are arranged to hold the valve open for twenty seconds each hour. During this time the valve can be adapted to deliver either 1 oz., 1½ oz. or 2 oz., according to amount of exit which is given to obtain 1/2 to 1 of exit. The largest size of aperture which the sac has at exit. There are smaller apertures which can be adapted to the valve by means of an appropriate nozzle. The clock, by its contrivance, can actuate, is often as is

any required number of electromagnets for a given number of seconds. This apparatus was tested in a severe case of compound fracture of the tibia, infected with *Bacillus pyocyaneus*, at the Royal Infirmary, Edinburgh, and found to irrigate the wound satisfactorily. The appliance should serve a useful purpose both as a labor-saving device and as a method of securing accuracy in the amount and regularity of the irrigations.

The Autonomic Nervous System in Sleep—Heilig and Hoff have made certain experiments in the clinics of Donath and Wagner-Jauregg in Vienna with the following results. It is known that in the waking subject a subcutaneous injection of adrenalin 1 mg. will cause a definite rise of blood pressure, but it was found that in the sleeping subject this rise does not take place. The various tests were made both in natural sleep and in paraldehyde or luminal sleep. An other test had reference to the content of calcium in the blood and it was learned that in sleep this is increased. Under provocative ingestion of 100 gms. glucose it was found that there is more blood sugar excreted in the urine of the sleeper than of the waking subject. The cerebrospinal fluid of the sleeper also contains more sugar and albumin and less chlorides than does the same fluid in the watcher. When the blood of the sleeper is perfused through the frog's heart the same difference is found in comparison with the watcher's blood. The significance of these finds is regarded as follows: the vascular tonus of the sleeper is diminished so that the walls of the vessels relax and their caliber is increased, as a result of which the blood stream becomes slower and the blood pressure falls. The mechanism is believed to concern primarily the autonomic nervous system which is thus modified during sleep.—*Klinsche Wochenschrift*, November 12, 1925.

Testicular Opothrapy in the Physical and Psychical Disorders of Celibate Women.—Humbert, in the article herewith noted (*Le Bulletin Médical*, October 24, 1925), refers chiefly to comparatively young women—around the age of thirty—who show nutritive and psychopathic disturbances and who have been anxious to marry. Some of them frankly believe that their maladies are due to celibate existence. In addition to indigestion and malnutrition they display causeless attacks of weeping, great irritability, psychasthenic manifestations such as phobias and fixed ideas, suicidal obsessions, prostration, fatigability, etc. If these patients do not improve under tonics and ovarian substance—which they usually require—the author places them on total testicular extract, given internally and never by injection or grafts. The benefit is said to be decided, though the results cannot be regarded as brilliant, judging by the case reports.

THE GOVERNMENT OF A PROFESSION

IV

In a profession so highly individualistic as medicine, initiative, originality, and the opportunity of personal accomplishment and ambition are essential factors for progress. These activating forces are the main springs to discovery and improved practice. There is no profession so ready to discard the old and take on the new as the medical profession—despite the popular belief to the contrary. But the new must first stand the test of truth applied by the profession through its scientific organizations before it receives professional acceptance. How short-lived is a medical or surgical fallacy because of the application of these principles! How acutely sensitive is the profession to the exploitation of new ideas to the lay public before they have been examined and adjudged sound! Why should this be? Because the lay public have too often been misled and victimized by the pseudo-scientists whose claims are such alloy of truth with the baser elements of fraud and empiricism that only the tests of scientific minds and experience can expose them. The rule which requires, before public exploitation of medical discoveries, a careful and searching test by the profession of the claims has doubtless saved the public many dollars and numerous lives.

But what redress has the profession against the man who today, within the law, defies this custom and masquerades before the public as its great benefactor for his own gain, who eschews professional standing with his brethren for the spotlight of the public's approval, who charges those who question his claims with motives of unworthy jealousy or conservatism? Such a man cares little for the severest judgment any censors can give—of professional excommunication, he makes capital of that and twists the motives prompting it to serve his own ends and prove his claim of professional jealousy.

The profession needs to be given more power to enforce its standards of honor and decency. The profession has always established high principles of conduct, but has failed to provide adequate machinery for the enforcement of those principles upon those unwilling to abide by them. A lay body is quite unable to cope with this problem, as it is one that peculiarly requires the background, the psychology, the standing and the experience of medical men.

For these reasons, among others, the proposed bill of the Medical Society of the State of New York seeks to establish a properly constituted and legally equipped committee that may consider all such grievances and apply adequate remedies.

CLAIMED DEATH AS RESULT OF TONSILLECTOMY

In this action the defendant, a specialist in nose and throat work, was charged with negligence in the performance of a tonsillectomy resulting in the formation of an abscess on the cervical glands and the subsequent death of the patient. The complaint charged that the defendant, as such specialist, on May 2nd was engaged to examine and remove the tonsils of a girl of about sixteen years of age, that the operation was performed at his office on May 12th, but that the defendant negligently and carelessly conducted himself in the performance of the operation and in the after-care, that at the time of the operation there was active suppuration in and about the tonsils and the defendant was negligent and careless in performing the operation in the presence of such active suppuration, that there was also pus about the tonsils at the time of the operation, and because of this condition the defendant was careless in

using a local anaesthesia. It was charged that the defendant was further negligent in permitting and instructing that the patient be taken from his office to her home on the day of the operation, that on May 16th he was charged with refusing to call at the home of the patient to attend and treat her, but advised that she be brought to his office, that when brought to his office he found a severe swelling on the left side of her neck and her teeth almost locked due to such swelling and stiffness, that at that time the defendant should have been apprised of the fact that the condition of the patient was serious, requiring prompt attention and care, and that he was negligent in not prescribing the necessary prompt care and treatment. He was also charged with negligence on the 17th and 18th of May in failing to call at the home of the patient, and again on the 19th until the evening, at which time it was claimed that the patient was

unable to swallow or open her mouth, that on May 20th it was necessary, because of the defendant's claimed negligence, to call in a surgeon, who operated upon the patient and that though they gave him notice, it was charged that he negligently failed to attend at such operation, that on May 25th, because of the defendant's alleged negligence, it was necessary to call another surgeon to operate upon the patient, at which time it was claimed that it was found that an abscess had formed which extended from the base of the skull downward to the upper part of the chest and backward beneath the muscles of the neck, and that the tissues of the neck were sloughing and the great vessels, including the jugular vein, were bathed in pus as far down as the chest, that on June 2nd, as a direct result of defendant's negligence, the patient died, and because of these facts damages were sought to be recovered against the defendant for the alleged causing of the death of the patient.

The defendant was a man of wide experience, specializing in nose and throat work. On May 4th the patient, accompanied by her adult sister, called on him at his office. He was given a history that the patient had had repeated attacks of tonsilitis for a period of years, the last attack having been four months prior. An examination at this time disclosed submerged tonsils, no acute inflammation and there was no pus present. He advised the removal of the tonsils, giving the people the choice of the performance of this operation either at his office, which was properly equipped for the same, at their home, or at a hospital. They selected that the operation be done at the physician's office and arrangements were made for the performance of the same on May 12th. On this date, the patient, accompanied by her sister, came to the defendant's office, where the necessary preparations were made by the defendant's assistant physician and his nurse. A local anaesthesia was administered by the assistant physician and the operation performed by the defendant without complications. There was very little bleeding, the tonsils being completely enucleated. After the operation the patient was put to bed in the retiring room and a special nurse assigned to attend her. The operation was performed in the morning, the patient remaining in the rest room all day and leaving for her home in the early evening. Instructions were given that when the patient arrived home she was to be put to bed, ice bags applied to her throat, frequent use of gargles and to be put on a liquid diet, and defendant to be informed as to the progress of the patient.

The defendant heard nothing further from the patient until May 16th, when she called at his office accompanied by her sister. An examination disclosed a clean-looking throat, normal tempera-

ture, slight pain on swallowing. On the day following, May 17th, the patient was seen at her home by the defendant's assistant, who reported that he found a slight swelling on the right side of the patient's neck. On May 18th she was seen by the defendant, and there was a swelling about the size of a hen's egg on the left side of the neck, which was tender. On May 19th the patient was again seen, together with the family physician. The defendant suggested to the family the calling in of a surgeon to open up the abscess if he found the same necessary. The family physician communicated with the defendant, stating that he was ready to open the abscess himself, but that the family preferred a surgeon, and that the family had made arrangements for a surgeon to call. When the defendant was notified by telephone that this operation was to be performed, he inquired if he could be of any assistance and was advised by the family physician that there was no assistance which he, the defendant, could render. Nothing further was heard by the defendant from the patient until May 25th when, by telephone, he was told that the patient was very sick. He immediately went to the patient's home and there met an eminent surgeon who had been called in consultation. The family physician was also present and members of the family. A history of the case was furnished by the defendant to the surgeon. Examination of the neck wound by the surgeon disclosed a large mass and pus discharging through the incision which had been made by the first surgeon who had been called in. The second surgeon was of the opinion that there was insufficient drainage and advised that the incision in the neck be enlarged. He did not, however, consider that the patient was in any danger. He further advised the family that the patient be sent to a hospital where he would operate upon her the following day. When inquiry was made by the patient's sister if the operation could wait until the following day, the surgeon stated that it would not jeopardize the patient at all and that it would only delay the convalescence by a day. Nothing further was heard from the patient by the defendant until about June 3rd, when the family physician, by telephone, told the defendant the patient was in the hospital in a critical condition, and that for him not to call upon the family as they felt embittered toward him. A few days thereafter the defendant heard that the patient had died.

This action was about to be reached for trial and after a conference with the plaintiff's attorney we were able to convince him that there was no negligence or carelessness upon the part of the defendant and that the death of the patient was not in any way due or attributable to any act of his, and thereupon a discontinuance of the action was consented to.

State Department of Health

Interesting Cases Found at Prenatal Consultations

During one week recently the prenatal consultation unit of the Department examined twenty-five expectant mothers in four different communities. Seventeen of the cases were new and eight were return cases. Of the new cases twelve were registered with and referred for examination by the family physician, five had not engaged a physician. Thirteen of the women were more than five months pregnant, while in only four was the pregnancy of shorter duration. One of the pregnancies was full term and a second almost so.

The interesting point in these twenty-five pregnancies was the large number of defects discovered. Fifteen of the women were suffering with high blood pressure, the systolic pressure ranging from 128 to 168. Fifteen had abnormal pelvises, three of them being of a major type which will require some sort of operative interference. There were four cases of suspected tuberculosis, three with cardiac disturbance, one case of demonstrable syphilis and one who had a sudden increase in weight with hydramnios. From the foregoing it will be quite evident to the reader that many of the patients suffered with more than one defect.

Of the five cases who had not as yet engaged a physician, one was in the ninth month, one in the eighth, two in the seventh and one in the fifth month of pregnancy. Three of these women were suffering with increased blood pressure (138 to 148 systolic), four had slight or moderate contractures of the pelvis.

No treatment is given to patients attending these consultations, if they are already in the hands of a physician he is notified and advised regarding the findings. If a physician has not been engaged for the labor the patient is given general advice about her condition, and she is urged to place herself in the care of a doctor at once, when this is done a full report of the patient is rendered to the physician.

These consultations have been held with an increasing degree of success in many communities of the State with the hearty cooperation of the local medical profession. Physicians in localities where these consultations are to be held are urged not only to refer cases but to attend themselves and observe the routine of a thorough prenatal examination.

Hospitals and Venereal Disease Control

The governing boards of hospitals with but few exceptions are adverse to admitting cases of syphilis and gonorrhea as such, when in the highly infectious state. From the public health viewpoint, cases of syphilis in the acute stage should be removed from the community and given intensive treatment while skin or mucous membrane lesions are visible, i.e., treated "not as a sexual malady but as an infectious malady to which no shame attaches, like small-pox" (Velthuyzen).

The October edition of *The Modern Hospital* states editorially, "one specific part of the public health program in which hospitals could and should actively engage is in the control of venereal diseases. In no particular is there a greater opportunity to do educational work, and certainly in the treatment of the venereal infections much may be accomplished if the work is thoroughly done."

The United States Public Health Service in commenting upon this editorial in its *Health News Release* says "Hospitals can render invaluable assistance to state, city and county health departments by giving the general public information regarding this gigantic health problem. With that end in view, not only hospital superintendents and the medical staff, but nurses, social workers and others coming in contact with the sick, should be educated to the point that they assist in promoting this valuable public health work." "Here," concludes the editor, "is a piece of work and a responsibility that the hospital field should and must meet at once."

Typhoid Outbreak at State Hospital—Carrier Discovered

An outbreak of eleven cases of typhoid fever recently occurred at the Rochester State Hospital. A general investigation of food handlers at the hospital was begun, and resulted in the discovery of a carrier, a man fifty-six years of age, who served as a dining-room helper. No history of ever having had typhoid fever could be obtained from him.

Five of the cases occurred among those who ate in the dining room in which this man served. The other six cases occurred in other buildings, but as some of the food from the first dining room went back to the general kitchen, it is thought that all the cases may have been due to this carrier.

NEWS NOTES

OTSEGO COUNTY MEDICAL SOCIETY

The Annual Meeting of the Otsego County Medical Society was held in the Elks Home, Oneonta, N Y The meeting was called to order by Vice-President R W Ford, in the absence of Dr Swanson The minutes of last meeting read and approved

Members present Drs F E Bolt, Worcester, E C Winsor of Schenectady, R W Ford, Otego, F L Winsor, Laurens, J P Hoyle, Fly Creek, W R Seeber, Milford, L C Warren, Franklin, J H Lindell, Cherry Valley, A H Bissell, C W Lanning, F J Atwell, H L Cruttenden of Cooperstown, M Latcher, D H Mills, Stanton Hendricks, E J Parish, W S Cooke, J C Smith, F H Marx, L S Lang, W S Dart, N W Getman and A H Brownell of Oneonta

After the usual business of the Society had been transacted the election of officers for 1926 was held The report of the Nominating Committee was received, and on motion the Secretary was directed to cast one ballot for the name as reported

The following were elected

President, Dr R W Ford, Otego, Vice-

President, Dr Marshall Latcher, Oneonta, Secretary, Dr A H Brownell, Oneonta, Censor, Dr J W Swanson, Springfield Center, Treasurer, Dr F L Winsor, Laurens, Delegate to State Convention, Dr A H Bissell, Cooperstown, Alternate, Dr L C Warren, Franklin

Dr Atwell read the paper prepared by the retiring President Dr Swanson He gave a review of the advance of medicine since he began to practice fifty-two years ago The paper was extremely interesting On motion of the Society a vote of thanks was extended to Dr Swanson Dr E J Parish presented the subject of Hip Joint Fractures, touching on the diagnosis and modern methods of treatment

Dr Arthur W Benson of Troy gave a talk on "tonsils," the various form of diseases and treatment of the same Both topics were followed by a general discussion

Dinner was served at 7 P M in the Elks dining room

A short business session was held after the dinner for the appointing of a special committee on legislation

WAYNE COUNTY MEDICAL SOCIETY

The Annual Meeting of the Wayne County Medical Society was held at Lyons December 8th, 1925 The meeting was called to order by President Sheldon at 11 30 A M The minutes of the last meeting were read and approved

The following members were present Dr Donnelly, J C Carmer, Allen, Winchell, Brandt, Sanford, Chase, Andrew, M E Carmer, Young, Smith, Johnson, Meyers, E W Carr, Sheldon, Robertson

Visiting physicians Dr Robert G Stuck, Wolcott, Dr Herbert E Sperry and Dr Frederick J Pratt, Williamson

Reports of the Secretary and Treasurer read and accepted and the footings ordered spread on the minutes

Amount received	\$487 74
Disbursements	378 51

Balance on hand	\$109 23
-----------------	----------

Average attendance of meetings, eighteen Two new members were taken in during the year, making thirty-five members in good standing

Following a recess for dinner at 12 o'clock, the meeting reconvened at 1 30 P M Election of Officers Motion made and seconded that L H Smith act as teller Carried

A separate motion was made, seconded, and carried that the teller cast one ballot for each of the following officers, and each officer was declared elected

President, Ralph Sheldon, Vice President, W H Sweeting, Secretary and Treasurer, D F Johnson, Censors, M E Carmer, H L Chase, A A Young, Delegate, L H Smith, Alternate, C H Bennett

Applications on membership of the following physicians were presented to be voted on at the next regular meeting

Frank G Stuck, Franklin L Meyers, Frederick J Pratt

A letter was read from the New York State Nurses Association in which recommendations were made for registering nurses Much discussion followed, and finally a motion was made and carried that the letter be laid on the table

SCIENTIFIC PROGRAM

The Veneral Peril, A A Young, Diagnosis, M E Carmer

Prognosis, H L Chase

All the papers were very interesting and brought out a liberal discussion

Meeting adjourned at 4 15 P M

MEDICAL SOCIETY OF THE COUNTY OF QUEENS

The annual meeting of the Medical Society of the County of Queens was held Tuesday, November 24th, 1925, at 8 30 P M, at Eagle Palace, Jamaica, with the President, Dr Courten, in the chair. After the minutes of the last annual meeting had been read and approved the following applicants, recommended by the Board of Censors, were elected to membership.

Drs Anthony B Debbie, Stephen Kiss, Maxwell Liberman, Harriet M White. Dr John J Salerno received on transfer from the Medical Society of the County of New York.

The amendment to the By-Laws, proposed at the preceding meeting, providing for the creation of an additional office in the society, a secretary and a treasurer, replacing the secretary-treasurer was adopted.

The Secretary-Treasurer then made his annual report, showing a membership of 299, the addition of 58 new members during the year, the loss of two members by death, one by resignation, four by removal from the county, with 14 members delinquent for the 1925 dues.

His report as treasurer showed a balance in the treasury of \$1,786 93, of which \$1,051 is deposited in the Queens County Savings Bank. An interesting item in the report concerned the publication of the Bulletin, the cost of which was \$232 67, and the receipts from advertisers \$162.

Dr Chalmers, for the Committee on new By-Laws, reported progress.

In the Scientific Session, the subject of the evening was "The New Medical Practice Act as Approved by the Council of the Medical Society of the State of New York," presented by Nathan B Van Etten, M D, President of the Medical Society of the State of New York and George W Whiteside, Esq, Counsel of the Medical Society of the State of New York.

Dr Chalmers, Dr McMahon and Dr Fleming shared in the discussion.

After a vote of thanks to the speakers of the evening, the meeting adjourned, and a collation was served. Attendance 75.

ULSTER COUNTY MEDICAL SOCIETY

The annual meeting of the Ulster County Medical Society was held at McCabe's restaurant Tuesday evening, December 1st.

The following officers were unanimously elected: President, Mary Gage Day, Vice-President, Frederick Snyder, Secretary, Frederick Voss, Treasurer, Chas B Van Gasbeek, Censors, James R Nelson, Mark O'Meara, Raymond Crispell, A A Stern, F Holcomb, Delegate, Luther Emerick, Alternate, Frank Eastman.

Dr Charles Cowing Zacharie of Marlborough and Dr Jacobson of this city were elected to membership.

It was unanimously voted to buy \$25 worth of Tuberculosis Christmas seals.

At the scientific session, Dr Ingalls made a short address in which he thanked all the members for their cooperation during his term as president, and he then turned the meeting over to Dr Snyder, the chairman of the scientific program.

Dr Snyder said some of our own members had taken the Inter-state Post Graduate Assembly tour the past summer, that they should have things well worth while to tell us, and he called on Dr M O'Meara, who gave a most interesting account of the trip from Montreal down the St Lawrence River, across the ocean and all the cities visited, Dublin, Glasgow and Paris. He spoke of the social features, but dwelt principally

upon the surgical clinics and hospitals visited. He considered the trip of the utmost importance.

Dr Norwood was the next speaker and while he was on the same trip the party was so large, over eight hundred, that they went over on different ships and the lectures on shipboard were, of course, by different specialists. When they landed they were in separate groups because they could not be accommodated in the hotels and hospitals. His description of the clinics of his section was most interesting and they, too, were principally surgical.

Dr Gifford was the last speaker and he emphasized more the medical clinics, which he found most valuable. In Paris they visited the Curie Institute and Madame Curie herself met them and made their visit to the institute most interesting to everyone interested in the use of radium in malignant diseases.

A general discussion of the nursing situation followed and Dr Chandler reported that the State Committee, of which he was a member had held one meeting in New York and were to hold another in Albany soon.

A framed copy of the certificate that the society is a member of the New York Board of Governors of the Gorgas Memorial Institute was handed Dr Day to serve as an inspiration during her term of office and to be passed to her successor. Refreshments were served.

* Special election will be held to fill vacancy

of its supply will have an unfavorable effect on the vigor of the human race and its resistance to disease

The article ascribes the cause of the diminution in the number of fish to the pollution of their breeding grounds with sewage and trade wastes. Many kinds of deep sea fish breed in the shallow water of estuaries which are polluted with sewage, and both the young and the old fish require an abundance of oxygen which is removed from the water by the decomposition of sewage. Shad, for example, have difficulty in swimming through New York Harbor on account of the lack of oxygen in the sewage-laden water.

A still greater menace to young fish life is trade waste, especially that containing acids. Young water animals are extremely susceptible to changes in the chemical composition of the water in which they live. Tadpoles, for instance, will seldom survive in tap water of New York City on account of the minute quantity of chlorine that is added to the water.

One remedy suggested at the conference was that the Government should extend the work of the artificial propagation of fish, as is already done successfully with lobsters. Much study will be necessary in order to discover the exact conditions under which blue fish, oysters, and other salt water animals breed.

It would be unfortunate if physicians and health departments lost all control of the disposal of sewage and trade wastes. They had full control of the disposal in the days when environmental conditions were supposed to be the principal causes of sickness. They should regain an increasing degree of control now that the indirect effects of improper disposal are demonstrated to be seriously unhealthful.

HOW MUCH SLEEP

The newspapers have been carrying extensive accounts of an experiment conducted at George Washington University, Washington, D. C., to determine the effects of loss of sleep. Seven students and two members of the faculty stayed awake for sixty hours, during which time they worked, studied, took exercise, and in other respects followed the ordinary active routine of waking hours.

The *New York Times* of December 13th gives a summary of the results written in popular form. The subjects seem to have felt only slight inconvenience, and at the end of the experiment they slept only a little longer than they usually did, and woke up refreshed and ready for more work.

The principal interest in the article is in its conclusions. Sleep is ascribed to an auto-intoxication with the products of metabolism. On the other hand, two of the subjects had an increased metabolism due to an over-active thyroid, and these habitually slept daily about two hours less than the others. Does increased metabolism also increase the perfection of the final oxidation of waste products in the body?

The principal conclusion of the article seems to be that sleep is largely a matter of habit, and the implication is that anyone can train himself to get along with little sleep,—three or four hours daily. This is not the attitude of physicians who deal with exhaustive states and weakened conditions. Sleep is a form of rest, and Americans, young and old, need more rest and repose. Longer hours of sleep, rather than fewer, is the almost universal advice of physicians at the present time. The important question is not how long can selected volunteers go without sleep during a single test, but how much sleep does the average person need day after day in order to maintain health and vigor of both the mind and the body.

"CURES" FOR COL COOLIDGE

The *New York Times*, December 13th, carries a short statement that Dr. Albert M. Cram of Plymouth, Vermont, says that nearly every mail brings to President Coolidge suggestions of "Sure Cures" for the infirmities of Col. Coolidge, his father. Everybody knows of some one who was seriously sick and who got well, and they ascribe his recovery to some one of the numerous things which were done to him. We are reminded of a horse doctor of our boyhood days who treated all sorts of domestic animals but always prescribed something new at every visit until the farmers asked him why he did not stick to one thing until he found out whether or not it was good for anything. The successful charlatans have only one remedy, and they use it for everything, and can point to numberless "cures" because nearly every one of their patrons survives, while doctors are frequently compelled to sign death certificates.

In the days of Hippocrates it was the custom for a sick man, on his recovery, to place an inscription in the temple stating what cured him, and doubtless the King also received as many suggestions as our President. The Father of Medicine probably learned much from a study of the votive tablets in the temples, but he must have been impressed with the utter futility of most of the remedies which he saw recorded.

THE DAILY PRESS

EUGENICS

The Magazine Section of the *New York Times* on Sunday, August 30th, contains an interesting interview with Luther Burbank in which he philosophizes regarding eugenics applied to human beings along the lines of its application to the improvement of species of plants. Burbank changes plants and fruits in regard to size, color, flavor, sugar content, hardiness, immunity to disease, and other characteristics by the simple process of fertilizing a plant with pollen from another plant which has the desired characteristic. After a few generations the quality becomes fixed in a new variety of plant.

The process may be considered to be one of evolution hastened, and guided, and intensified so that in the course of a dozen generations the development is as great as that which would occur in as many centuries or milleniums under natural conditions.

The work of Luther Burbank recalls that of his great predecessor, Gregor Mendel, a priest and abbot of a Moravian monastery who was interested in his garden more than theology. In 1865 he published his experiments and observations on the cross fertilization of sweet peas, and stated the principles of heredity which are known as Mendel's laws, and which are found to apply to other plants and to lower animals.

The same laws apply equally well to man himself, not only to his physical body, but also to his mental capabilities and traits.

Dr C. B. Davenport has published his observations on one phase of heredity in man's physical characteristics in an article on "The Inheritance of Stature," published in *Genetics*, Volume 2, page 313, July 1917, and reprinted as Bulletin No. 78 of the Eugenics Record office, Cold Spring Harbor, N. Y. Dr Davenport has made hundreds of measurements of the elements of stature,—total height, sitting height, head and neck, torso, femur, fibula, and has showed how these characteristics are transmitted by parents to children in accordance with the same laws that control the inheritance of plant characteristics.

Psychiatrists and psychologists have abundantly demonstrated that the same principles of heredity apply to mental characteristics, both as to unusual ability, and its opposite, degeneracy and unsocial tendencies. Almost the only scientific application of human eugenics has been in the investigation of cases of insanity and mental defectiveness, and to a slight extent in the isolation of a few mental defectives. Some states have passed laws authorizing the sterilization of criminals, but a feeling of sentimentality has pre-

vented their application, except in rare instances. The agitation regarding contraception is a negative phase of the same idea.

A man is the product of both heredity and environment or teaching. Environment has been emphasized to the neglect of heredity. The church and the school have taught the equality of all men, and magazine articles and advertisements proclaim the quarter truth that anybody can cultivate a photographic memory and a captivating personality. Pride in good ancestry has the very real basis in the transmission of desirable qualities of body and mind, and also of morals.

The slowness of man's development from infancy to adult life,—twenty-five years at least,—prevents the effects of heredity on the human race from being vividly apparent, and it is probable that for many generations to come men of large mentality will continue to be ensnared by pretty girls without brains, and that folks will wonder at the mediocre ability and loose morals of their offspring. Education in eugenics is necessary if the race is to attain the heights of progress of which it is capable.

POLLUTION BY SEWAGE

Departments of health no longer seek the principal causes of sickness in environmental conditions, and as a result they are advising that the control of sewage, garbage, and other wastes is an engineering problem that belongs to other departments than that of health. The leaders of larger health departments have often minimized the effects of environmental conditions other than those directly affecting drinking water and milk, and have discouraged local health officers in their efforts to control environmental conditions.

While garbage and sewage may not be a direct cause of much sickness yet they do have a great effect on health indirectly. The *New York Times* of December 13th contains an article on the effect of sewage on sea fish. This subject was discussed at the Annual Dinner of the Middle Atlantic Fisheries Association on December 12th in the Hotel Astor, New York City. The speakers discussed the great reduction in the number of salt water food fish. Blue fish, they say, are only one-tenth as plentiful as formerly, and sturgeon are becoming rare. If the diminution continues, fish will become a rarity in the markets. Oysters, crabs, and lobsters are also decreasing in numbers.

The indirect effects on health are easy to trace. Fish has been a source of protein food that has been both abundant and cheap, and a diminution

THE TREATMENT OF DIABETES MELLITUS IN CHILDREN *

By ROGER H DENNETT, B S, M D,

NEW YORK

OUT of the mass of literature upon Diabetes Mellitus since Banting's revolutionary discovery, it appears that the general practitioner has gained the impression that the present treatment of diabetes is an extremely complicated matter. On the contrary, in comparison to the intricate mazes of infant feeding which have gradually been simplified and are even approaching standardization, the treatment of diabetes is simple indeed.

It will be the object of this paper to present the matter in as simple a form as possible, so that the physician who has not had the opportunity of following the entire literature may possibly make a start in treating this common diseased condition. There are so many cases of diabetes that need the physician's care, and who cannot reach the specialist—and in my opinion there are not a few children who die in diabetic coma in whom the diagnosis has never been made.

The diabetic problem is simpler in young children than it is in adults, first because the child is always under the supervision of a mother or nurse, and he has to eat the food that is given him. He has less temptation to deviate from the diet because of this supervision. He leads a regular life with less interruptions, has his sleep at stated hours, and his food at more regular intervals. Mental strain is avoided and it is a simple matter to regulate his exercise.

Formerly the high mortality of diabetes in children was discouraging to parents and physicians alike. Now everyone takes hope for not only is there definite promise of saving life and of making the dwarfed, emaciated child into a normal, healthy individual, but in certain favorable cases there is the possibility that the pancreas will so regenerate that insulin may be discontinued.

Just as soon as possible after the insulin and dietetic treatment is instituted, it is our object to get the urine sugar-free and keep it so. Even a

small amount of sugar in the urine for a few hours a day is an added burden to the pancreas and is evidence that this organ is being damaged. Our only hope of getting rid of the hypodermic life lies in keeping the urine sugar-free. As soon as the diet is sufficient to maintain the proper growth of the child, and as soon as the urine is sugar-free and the blood-sugar near normal limits, then must the insulin be gradually reduced, always with the greatest care that the sugar does not re-appear in the urine or become increased in the blood and that the normal increase in weight and growth is continued.

When instituting treatment in a case of diabetes, put the child to bed, take the twenty-four-hour specimen of urine, get the number of grams of sugar voided in twenty-four hours and administer in twenty-four hours one quarter of the number of units of insulin as there are grams of sugar excreted. The child passing two thousand cc. of urine with 4% sugar, loses eighty grams of sugar daily. The initial daily dose of insulin would be one-quarter of this, or twenty units. This is usually too small a dose to entirely free the urine of the sugar or reduce the blood-sugar to normal, but it is a safe dose for the beginning. This rule does not apply to children with the severer grades of Acidosis, nor children in coma, which will be discussed later.

Put the child on the first diet for its age and weight in the list appended below. Compute the blood-sugar before diet or insulin are instituted. If the blood-sugar is high, the dosage of insulin may be increased with safety. If, in twenty-four hours, the sugar in the urine is not rapidly diminishing, or if in forty-eight hours the urine is not sugar-free or nearly so, increase the dosage of insulin. The patient started with twenty units may have thirty in twenty-four hours. In another forty-eight hours, if the urine is not sugar-free, still another five units of insulin may be added to the daily dosage, provided the blood-sugar has not been rapidly lowered to within normal limits. If the blood-sugar is watched carefully the insulin may be increased until the urine is sugar-free.

BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review as dictated by their merits, or in the interest of our readers.

- A COMPEND OF DISEASES OF THE SKIN** By JAY FRANK SCHAMBERG, A B, M.D. Seventh edition, revised and enlarged 16mo of 316 pages with 119 illustrations Philadelphia, P. Blakiston's Son and Company, 1925 Cloth, \$2.00 (Blakiston's Compendis)
- FUNDAMENTALS OF BIO-CHEMISTRY** In Relation to Human Physiology By T. R. PARSONS, B.Sc., M.A. Second Edition 12mo of 295 pages Baltimore, Williams and Wilkins Company, 1925 Cloth, \$3.00
- BAILEY'S TEXT-BOOK OF HISTOLOGY** Revised and rewritten by OLIVER S. STRONG, A.M., Ph.D., and ADOLPH ELWYN, A.M. Seventh Edition, profusely illustrated William Wood and Co., New York, 1925 Price \$7.00
- PITFALLS OF SURGERY** By HAROLD BURROWS, C.B.E., M.B., B.S., F.R.C.S. Second Edition. William Wood and Co., New York, 1925 Price \$4.50
- MAN HIS MAKING AND UNMAKING** By E. BOYD BARRATT, M.A., Ph.D. Thomas Seltzer, New York, 1925 Price, \$2.50
- HEXOSAMINES AND MUCOPROTEINS** By P. A. LEVENE, The Rockefeller Institute for Medical Research, New York. Longmans, Green and Co., 1925 Price, \$3.75
- WILLIAM CADOGAN (His Essay on Gout)** By JOHN RUHRAH, M.D., Professor Diseases of Children, University Maryland Paul B. Hoeber, New York, 1925 Price, \$1.50
- SUBMUCOUS ENDOCAPSULAR TONSIL ENUCLEATIONS** With discussion of the evolution of knowledge of the tonsil as a disease producing factor and various methods of enucleation Excerpts from Clinics of Charles Conrad Miller, M.D. The Oak Press, Chicago
- OTOLOGIC SURGERY** By SAMUEL J. KOPETZKY, M.D., F.A.C.S., Professor Otolaryngology, Polyclinic Medical School and Hospital, N. Y. City 102 illustrations, 4 color plates, 21 charts Paul B. Hoeber, New York, 1925 Price, \$8.00
- ARCHIVES OF CLINICAL CANCER RESEARCH** July 1925 Volume 1 No 3 Published under the auspices of the New York City Cancer Institute, Department of Public Welfare, City of New York
- THE MEDICAL DEPARTMENT OF THE UNITED STATES ARMY IN THE WORLD WAR. Vol. XV, Statistics** Prepared under the Direction of Maj. General M. W. IRELAND, Surgeon General Government Printing Office, Washington, D. C. 1925
- A SYNOPSIS OF MEDICINE.** By HENRY LETHBRIDGE TIDY, M.A., M.D., B.Ch. (Oxon.) F.R.C.P. (Lond.) Assistant Physician St. Thomas's Hospital, Physician to the Royal Northern Hospital Fourth Edition, Revised and Enlarged William Wood and Co., New York. Price, \$6.00
- RADIOGRAPHY** A Manual of X-ray Technique, Interpretation and Therapy By CHARLES D. ENFIELD, M.D., F.A.C.P., Roentgenologist St. Anthony's Hospital and Norton Memorial Infirmary, Louisville, Ky. 194 illustrations P. Blakiston's Son & Co., Philadelphia.
- A SYSTEM OF CLINICAL MEDICINE,** dealing with Diagnosis, Prognosis and Treatment of Disease for Students and Practitioners By THOMAS DIXON SAVILL, M.D., Lond. Seventh Edition William Wood and Co., New York Price, \$9.00
- TAYLOR'S PRACTICE OF MEDICINE.** By E. P. POULTON, A.M., M.D., Oxon., F.R.C.P., Lond., Physician Guy's Hospital, with assistance of C. PUTNAM SEYMOUR, M.A., M.D., Oxon., F.R.C.P., Lond., Assistant Physician for Nervous Diseases, Guy's Hospital, H. W. BARBER, M.A., M.B., Camb., F.R.C.P., Lond., Physician charge Skin Dept., Guy's Hospital, Thirteenth Edition, 48 plates (8 colored), 93 text-figures. P. Blakiston's Son & Co., Philadelphia, 1926 Price, \$9.00
- MEDICAL HEREDITY** Distinguished Children of Physicians (United States to 1910) By WILLIAM BROWN, Ph.D., M.D., Professor Neurology, Long Island Medical College, Consultant Brooklyn State Hospital, with introduction by CHARLES B. DAVENPORT, B.S., A.M., Ph.D. Norman Remington Co., Baltimore, 1925 Price, \$4.00
- ATLAS OF DISEASES OF THE SKIN** By Prof. G. RIEHL of Vienna and Prof. LEO V. ZUMBUSCH of Munich, with diagnostic and Therapeutic Notes by JOHN B. LUDY, A.M., M.D., Col. Med. O.R.C., U.S. Army, Dermatologist, Lankenau and Methodist Hospitals, Philadelphia. Three parts Part I, Infectious Diseases of the Skin, 69 colored illustrations, Part II, Inflammatory Diseases of the Skin, 65 colored illustrations, Part III, Atrophies, New Formations Hypertrophies, 61 colored illustrations all taken from life. P. Blakiston's Son & Co., Philadelphia
- ULTRA-VIOLET RADIATION AND ACTINOTHERAPY** By ELEANOR H. RUSSELL, M.D., B.S., Dunelm and W. KERR RUSSELL, M.D., B.S., Dunelm Goyer Scholar, University Durham, 1914, late Surgeon, Special Military Surgical (Orthopedic) Hospital, Newcastle, forewords by SIR OLIVER LODGE, F.R.S., D.Sc., LL.D. and SYDNEY WALTON, C.B.E., M.A., B.Litt. William Wood & Co., New York and E. & S. Livingstone, Edinburgh Price, \$3.50
- SWANZKY'S HANDBOOK OF THE DISEASES OF THE EYE AND THEIR TREATMENT** Thirteenth Edition. Edited by LOUIS WERNER, M.B., F.R.C.S.I., Sen. Mod. University of Dublin. Surgeon to the Royal Victoria Eye and Ear Hospital Illustrated P. Blakiston's Son & Co., Philadelphia, 1925 Price, \$6.50
- HANDBOOK OF PATHOLOGY** By C. Y. WANG, M.D., Edin., B.Sc., Vict., F.R.C.P., Edin. with two hundred and eighty-two illustrations William Wood & Co., New York. Price, \$7.00

der the skin. Opinions vary as to the advisability of one large dose of insulin intravenously or repeated smaller doses subcutaneously. I prefer the latter. In a child of over five years of age, ten units of insulin may be given every four hours if the blood-sugar is high. Under that age, five units every four hours is safer at the beginning, but in grave cases in coma, the larger dose should be used if the patient fails to respond to treatment. It is one of the joys of medical practise to see these children who formerly came into the hospital to die, return to consciousness and sit up in bed and ask for food,—often within twenty-four or forty-eight hours.

Blood-sugar determinations are essential to the proper treatment of diabetes, if we would avoid sugar-shock and the dangers of insulin. It is necessary to take the blood for blood-sugar before the first dose of insulin is administered. In severe cases it is not necessary to await the laboratory report before instituting treatment, since the clinical evidence of acidosis with large amounts of sugar in the urine is sufficient. Blood-sugar is not of aid in the prognosis, but its chief help is as a guide in the treatment. The blood-sugar may be taken subsequently only as guidance is needed in the insulin and dietetic treatment.

I wish the laboratory man could use fewer decimals, particularly in their blood chemistry, for I believe decimals confuse the busy practitioner, and are difficult to remember. Some speak of the normal blood-sugar as 1 to 130 grams to the liter, others speak of 1 to 130 grams to the 100 c.c. How much easier it would be to remember that the normal blood-sugar in round numbers is 100 to 130 to the hundred liters. Then he who runs may read that the blood-sugar of 500 is five times over the normal, and the blood-sugar of 90 is getting below the normal, and the blood-sugar of 70 approaches the danger-point and may cause sugar-shock.

Acidosis, although diagnosed by acetone and diacetic acid in the urine and by acetone odor of the breath and the well-known symptomology is best measured by the carbon-dioxide (CO_2) combining power of the blood. The carbon-dioxide is normally 50 to 70. Under 40 means moderate acidosis, 25 to 30, severe acidosis, and 15 to 20 may be fatal.

Severe diabetes is best treated in a hospital, until it is under control. It is perfectly remarkable however, how the most seemingly unintelligent and helpless mothers will grasp the details of measuring food, examining urine and administering hypodermics. Mothers can readily be taught these procedures if a trained nurse cannot be put in charge. Syringes, made for insulin only,

simplify the measuring of the dosage, boiling of the needle and syringe makes asepsis safe.

Most children with frank Diabetes Mellitus require insulin. Transitory Glycosuria and Renal Diabetes are naturally not included in this group. With these exceptions the mild cases of diabetes which are so often observed in adults and which can be controlled by diet alone are seldom if ever seen in children. It is therefore expedient to begin the administration of insulin without delay if the blood-sugar is high. Children also require relatively larger doses of insulin than adults. It is not unusual to see a child under five years of age weighing around 30 pounds that requires thirty to thirty-five units a day long after the initial treatment with larger amounts has cleared up the acidosis and other grave symptoms. It is a well-known fact that the daily amount of insulin does not depend upon the size of the individual or the body weight.

Another handicap that appears to be the unhappy lot of the child is the larger amount of food relatively that is necessary on account of growth. Whereas many adults require only thirty to forty calories per Kilo body weight or fourteen to eighteen calories per pound the growing child needs twice that amount and some emaciated, dwarfed children with long standing diabetes need even three times that amount. Children have an increased liability to acidosis, in fact throughout childhood acidosis is a frequent complication of their various diseases, and even children who are otherwise well not uncommonly have recurrent attacks of vomiting, diarrhoea or fever accompanied by acidosis. This liability to acidosis adds to the difficulty in displacing the carbohydrates with the fats to so great a degree as is possible in adults. Even well children do not assimilate and utilize fats as easily as adults and it is not safe to run up the ratio of carbohydrates to fats as high as one to three as in advocated for adults by some authorities.

I wish to place especial emphasis upon the often reiterated statement that the dietetic treatment of diabetes is just as important now as it was before the days of insulin. So far as children are concerned the diet is even more necessary than formerly because when aided by insulin the outlook is so hopeful. In this paper the writer has not devoted much space to the actual diets used because most text-books and manuals go into the subject so much more thoroughly than would be possible in a paper of this scope.

The diets of Mosenthal appended seem very well suited to children, as well as being presented in a very simple and easily understandable form both for patient and physician.

As soon as the sugar has disappeared from the urine the very low initial diet should be increased, giving the second diet on the appended list, and if the urine remains sugar-free, increase the diet every few days up to a point where it is sufficient to maintain the proper growth and increase in weight.

At this stage, where the case is progressing favorably, the daily dosage of insulin may be decreased, dropping off one or two units at a time, until in the most favorable cases the insulin reaches the vanishing point and may be discontinued. So far only the most favorable cases have been described. Often there are interruptions, and occasionally one's resources are taxed more than above description would indicate. Where the outcome is not so fortunate, which really constitutes the majority of cases, the minimum dosage of insulin which will keep the urine sugar-free and the minimum diet which permits the proper growth and gain in weight, must be continued.

Divide the total daily quantity of insulin into three doses just as the food in the diet is divided into three meals. Give insulin subcutaneously, one-half hour to twenty-minutes before each of the three meals, have the breakfast early, the night meal late, and the noon meal half way between. Seven, one and seven o'clock are not bad hours.

All of the urine voided in twenty-four hours should be saved and examined for sugar. It should be divided into three lots, each of which is examined separately, the first lot being from 7 A M. to the noon meal, the second lot from noon to 7 P M., and the third lot being the night specimen. If sugar appears in any one of these specimens, say in the night specimen, a small amount of the noon insulin may be taken away from that dosage and added to the night dose. If this does not suffice to stop the output of sugar at night, it is occasionally necessary to give a small dose of insulin at 10 or 11 P M. With various manipulations of this sort small amounts of sugar occurring at a definite time each day, when the urine for the rest of the day is sugar-free, may be eliminated without increasing the twenty-four-hour dosage of insulin.

It is the ambition of most diabetic patients to lessen the number of hypodermic injections of insulin as soon as possible, since the injections, if not painful, are, to say the least, a nuisance. As soon as the eventual diet is established, and the proper dosage of insulin necessary to keep the urine sugar-free is determined, the total daily dosage of insulin may be divided into two instead of three doses and given before the morning and the night meal. A patient getting ten units three times a day may therefore have fifteen units twice a day. Subsequently the daily dosage is gradually diminished to ten units, or five units

night and morning and still later it is often possible to give one daily dose of ten units before the morning meal. In the most favorable cases from this point on, the insulin can be cut down a unit at a time until it is discontinued if the urine remains sugar-free.

So far only the milder types of diabetes have been discussed. It is to be hoped that in the future the educational value of the lay manuals and articles in lay magazines upon diabetes will so educate the public that they may early recognize the beginning symptoms of this dread disease. There is no question that the children who are seen and properly treated within one or two weeks after the onset, are the patients that have the best chance, and these are the rare cases that may progress favorably after a time without insulin. Such cases do occur, although we have not had insulin long enough to determine whether recurrence of the disease is inevitable in children. Some authorities claim that it is. I have had but one case that has continued over a considerable period without insulin after a symptomatic recovery from a severe but early recognized diabetes which had been treated with insulin.

Practically all severe cases of diabetes in children are accompanied by acidosis, and many of them are in or near coma when first seen. It is difficult to fix the time of onset of diabetes, but children are often seen in whom the onset has seemed exceedingly abrupt, children who have been judged by their parents to be entirely well until coma is imminent or present.

The treatment of Diabetic Acidosis deserves discussion by itself. The principal source of acetone bodies in the blood is the fat. Insulin not only brings about the utilization of sugar, but corrects the acidosis, since the proper utilization of starches and sugars is necessary to the complete combustion of fats. In severe acidosis the administration of carbohydrates in conjunction with insulin not only protects the patient from sugar-shock, but hastens the elimination of acetone bodies in the blood and tissues. During the first day of treatment of a severe case of Diabetic Acidosis it is necessary to give large amounts of orange juice or glucose, or both. If the patient can swallow and is not vomiting, it is just as well to give these by mouth. One to three quarts of a 5 per cent glucose solution may be given in twenty-four hours. The fluid is usually badly needed. Or a pint of orange juice may be given and is usually much more readily taken than glucose. In addition to the orange juice large amounts of water are necessary. Weak tea is useful where the caffeine is needed for stimulation. Karo Syrup, 2 ounces to the pint of water, gives approximately 5 per cent glucose solution. Patients who cannot swallow must have glucose (pure dextrose) introduced intravenously, into the abdominal cavity, into the rectum or un-

The stools contained much pus and blood, but no protozoa. A roentgenogram of the colon was suggestive of chronic ulcerative colitis, and a later one was typical of the condition (Fig 1). A culture of the urine revealed colon bacilli. A proc-

he had developed an acute obstruction for three days when the passage of fecal material was accompanied by a large amount of black fluid. No light blood or pus was seen in the stool at any time. Complete recovery had occurred in six

FIG 1 Roentgenogram of the colon, typical of chronic ulcerative colitis

toscopic examination made at a later stage showed rectal ulceration. The patient improved somewhat until a perirectal abscess developed, as the result of which she became rapidly worse, and the skin trouble returned. Because of the poor healing of the rectal disease and the general loss of strength, she was given a transfusion of 300 c.c. of blood, with immediate improvement in her general condition. The stools became less frequent and showed no blood. Proctoscopic examination two weeks later showed very definite improvement. A roentgenogram of the colon indicated slight improvement although definite changes were still visible. She gained 4 pounds during the last month at the hospital and when she left weighed 67 pounds.

Nine months later the patient returned weighing 101 pounds, having had slight diarrhea with blood-streaked stools on two occasions. A proctoscopic examination made at this time was negative, but a roentgenogram of the colon still showed definite evidence of chronic ulcerative colitis (Fig 2). A recent letter, received nine months after her second examination, stated that there had been no return of this trouble.

Case 2—A boy, aged eleven, living in Minnesota, came to the clinic November 6, 1923, complaining of diarrhea. His history was negative except that four years before, following pneumonia

FIG 2 Later roentgenogram, showing improvement

weeks. The tonsils had been removed at the age of five. In April, 1923, he had begun to complain of abdominal pain and one week later began having four or five loose movements, usually preceded by pain. The diarrhea had persisted in spite of all treatment. The mother had noticed that the stool was blood-streaked.

At examination the child appeared to be undernourished and had evidently lost weight recently. The general examination was essentially negative. The hemoglobin was 76 per cent, the erythrocytes numbered 4,650,000, and the leukocytes 7,600. Repeated examinations of the stool showed pus and erythrocytes, but no parasites or ova. Proctoscopic examination revealed the granular, glazed mucosa usually associated with chronic ulcerative colitis, extending up into the sigmoid, without contraction of the bowel. A roentgenogram of the bowel at this time was negative.

The patient entered the hospital, but, in spite of dietary measures and iodine and kaolin medication, continued to lose weight, the diarrhea remaining about the same. He complained of headache, and had several spells of vomiting when food was forced. After one month in the hospital he lost 10 pounds, and the diarrhea was about the same, if not worse. The general condition became rather alarming. In spite of the apparently good

CHRONIC ULCERATIVE COLITIS IN CHILDHOOD *

By HENRY F HELMHOLZ, M.D.,
ROCHESTER, MINNESOTA

FOUR cases of chronic ulcerative colitis in children, observed during a period of two and one-half years, were reported in a previous paper.³ As this is the only published account of such cases, it seemed possible, as so frequently happens, that a group of unusual and similar cases had all appeared at the same time. It is now two years since my first report, and it is possible at this time to add seven new cases to the series. Two cases were seen in the second half of 1923, three in 1924, and two thus far in 1925.

REPORT OF CASES

Case 1—A girl, aged ten, came to the clinic from Wisconsin June 21, 1923, with a complaint of skin and bowel trouble. She had had measles, pertussis, and scarlet fever, and her tonsils had been removed three years before. The present illness had begun in February, 1923, with diarrhea, there were seven or eight greenish stools containing a large amount of mucus streaked with blood

daily. For three weeks there had been intermittent fever as high as 103°, then gradual improvement, until at the end of seven weeks the patient was up and about, but still had three or four loose blood-tinged stools daily. During the two weeks before examination fever had reached 102°, and the passage of stools had frequently been associated with tenesmus. Coincident with the onset of the bowel trouble, small ulcers had appeared in the mouth. One week before, the face and hands had broken out.

At examination the patient had a temperature of 101°. The blood count revealed hemoglobin 50 per cent, 3,960,000 erythrocytes, and 15,000 leukocytes. There were numerous pustules on face, body, and hands, and red areas over the knees, wrists, and fingers, with some tendency to pustulation in areas on both hands. The condition was diagnosed as impetigo, possibly pemphigus. The general examination was negative except for tenderness in the region of the rectum.

mild diarrhea and some pain. The stools were thin and explosive. The diarrhea had become gradually more marked and the pain worse. He had passed three or four stools a day and an equal number at night. Shortly before coming to the clinic the stools had become watery and streaked with blood. In spite of treatment, the condition had remained about the same, being definitely worse in the winter. He had lost weight. Numerous stool examinations before coming to the clinic had showed blood and mucus but no parasites, except on one occasion when it was thought that an ameba was found.

The boy was rather pale and 10 per cent underweight. The hemoglobin was 65 per cent, the erythrocytes numbered 3,000,000, and the leukocytes 7,800. The von Pirquet and Wassermann reactions were negative. A roentgenogram of the colon was typical of chronic ulcerative colitis with a great deal of spasm in the ascending colon and hepatic flexure (Fig 4). Proctoscopic examination revealed diffuse hyperemia of the rectosigmoid mucosa with the typical granular, glazed appearance of ulcerative colitis.

FIG. 4 Roentgenogram of the colon showing spasm in the ascending colon and hepatic flexure

The boy was hospitalized and given the usual treatment of tincture of iodine, minims 5, and kaolin, but in spite of this and dietary measures, he became gradually worse. Nineteen days after admission he was given a transfusion of 450 c.c. of blood which proved very beneficial. The bowel movements decreased markedly in number, and blood disappeared from the stool. There was a gain in weight, and proctoscopic examination showed some improvement, although a roentgenogram showed no change. The child's weight,

which had dropped from 96 to 88 pounds, rose to 97 pounds just before dismissal.

Case 5—A girl, aged eleven, came to the clinic from Nebraska, complaining of bleeding from the bowels. She had had measles, mumps, pertussis, scarlatina, and influenza in 1915, then had apparently been well until March, 1923, when she complained of severe abdominal cramps. Cathartics had been given without effect. An enema had returned clear water and bright red blood. The patient had continued to have large quantities of blood in scanty stools for ten days. For six weeks the bloody stools had continued for three or four times a day, the hemoglobin falling as low as 15 per cent, and the erythrocytes to 1,500,000. The condition gradually improved, and by the end of six weeks the blood in the stools had disappeared. Then the patient had been practically well for ten days. In the middle of August she had begun to complain of headache and loss of appetite. Following a week of constipation, an enema brought forth large amounts of blood, again with a good deal of pain, and bloody stools. This condition had lasted for six weeks. She had improved rapidly and had gone home in fairly good shape. The last attack had started four days before coming to the clinic with considerable blood in three or four stools a day.

On admission the girl was rather healthy looking and 2 pounds overweight. The physical examination was negative except for pain and tenderness on palpation of the abdomen. She complained of a great deal of pain on rectal examination. The hemoglobin was 65 per cent, the erythrocytes numbered 4,000,000. A roentgenogram of the colon was negative. Proctoscopic examination showed the mucosa of the rectum and sigmoid to have numerous small superficial ulcers on an inflammatory base, the involvement being more marked in the sigmoid. A diagnosis was made of chronic ulcerative proctosigmoiditis.

The patient was sent to the hospital where on a soft diet she continued to have from five to seven bloody stools daily, the blood frequently being clotted. She lost 3 pounds in four days and had no appetite. A transfusion of 450 c.c. of blood was given, after which the bowel movement decreased and contained smaller amounts of blood, although the pain was about as severe as before. Culture of a stool showed typical streptococci. A second transfusion was given and about a week later the stools were only occasionally streaked with blood. The amount of blood was definitely less but there was not the striking result that there had been in the other cases, particularly with regard to the disappearance of blood and improvement in the general condition. Operative interference was suggested but not urged.

Case 6—A girl, aged twelve, from Oregon, came to the clinic in February, 1925, complaining of bloody dysentery. She had had influenza at the age of four, and the tonsils had been removed

state of his blood, he was given 400 c.c. of his mother's blood with immediate and striking effect. His appetite returned, and within twenty-four hours the stools became pasty, free from blood, and normal in number and color. During the next week he gained 65 pounds and was dismissed greatly improved.

He returned to the clinic in April, 1924. He had been well until about the first of March when, following a cold, the stools had again become loose, watery, and tinged with blood, and numbered four or five daily. There was marked general weakness. As this time a roentgenogram of the colon definitely indicated ulcerative colitis (Fig. 3). Kaolin, 2 drams, was given three times a day.

FIG. 3 Roentgenogram taken at the second visit, showing chronic ulcerative colitis (Case 2)

In July, 1924, he returned again with the condition apparently practically unchanged. He had gained no weight since his last visit. The roentgenogram showed chronic ulcerative colitis with some spasm in the cecum and terminal ileum, but proctoscopic examination revealed very marked improvement. Cultures were made from the stool, a diplococcus was isolated, and a vaccine prepared. One-tenth of a cubic centimeter was given for a week then the amount was increased by 0.1 c.c. at each dose until 1 c.c. was given.

On the patient's return in November, 1924, he was in fairly good condition, but had frequent stools, about as before. Because of the splendid reaction to his first transfusion he was given another without the striking result seen before. There was a severe reaction because it was given seven days after a small-pox vaccination. It was

given at this time because the patient lived at a distance and could not remain long. At present the boy is going to school but feels tired and still has two or three watery stools daily, with a little blood occasionally.

Case 3—A boy, aged eight and one-half years, living in Minnesota, came to the clinic January 29, 1924, complaining of bloody diarrhea. He had had measles, mumps, pertussis, scarlatina, and influenza in 1922. Since April, 1923, he had had recurring headaches. The bloody diarrhea began in September with six to eight bloody stools daily. This condition had lasted three or four days, and since then the stools had been constantly loose or watery and contained blood. Headache had been less marked since the onset of diarrhea.

The patient was a fairly healthy looking boy, 10 per cent under weight. His temperature was normal. The tonsils were slightly enlarged, but the general examination was negative otherwise. The blood count showed 71 per cent hemoglobin, 4,320,000 erythrocytes, and 9,600 leukocytes, with a normal differential count. The Wassermann and tuberculin reactions were negative. *Entamoeba histolytica* was found in one stool only, and *Entamoeba coli* was found in a later specimen. Pus and blood were present. Culture of the stool was repeatedly negative for typhoid and dysentery bacilli. Proctoscopic examination revealed a mild granular appearance of the mucosa. The diagnosis was granular proctitis. A roentgenogram of the colon was negative.

The patient was given emetin hydrochlorid, 0.025 grain, and coal-oil enemas, but as the stools were constantly negative after the first injection, the specific medication for *Entamoeba histolytica* was discontinued. In spite of negative findings, the condition became progressively worse. One month after admission the child developed a throat infection and the anemia became more severe with exacerbation of symptoms. A second roentgenogram of the colon, taken one and one-half months later, was definitely positive for chronic ulcerative colitis, although proctoscopic examination showed only a mild proctitis. At times, the stools would improve, then for no apparent reason they would become watery with definite streaks of blood. At about this time a transfusion of 150 c.c. was given. There was definite improvement in the number and character of stools for a short time, but before the patient left the hospital they again contained a considerable amount of blood. Roentgenograms taken before dismissal disclosed the condition unchanged, proctoscopic examination disclosed a mildly granular condition of the mucosa but no active ulceration.

Case 4—A boy, aged twelve, living in Minnesota, came to the clinic complaining of diarrhea. Two years before, he had begun to have stomach trouble with much belching of gas and the passage of gas by rectum, accompanied at first by a

fluctuation and exacerbation with acute infection. As in Case 1, local lesions in the mouth and on the skin, and particularly perirectal infection, are usually of bad prognostic import.

The anemia is usually not so marked as would be expected from the constant loss of blood, and the nutritional condition is remarkably good considering the diarrhea. The diagnosis rests essentially on the proctoscopic findings of a glazed mucous membrane and, in the later stages, on a granular appearance of the mucosa. The roentgenograms are pathognomonic of the disease, the colon appearing smooth and without haustra throughout the diseased portion. Later there is definite contraction with narrowing. The lesions seem to develop in the rectum and ascend to the cecum, but rarely if ever involve the ileum.

COURSE

The responses to recent letters sent out to eight of the patients still living indicate that even in the most severe and protracted cases there some signs of improvement. In only one case has there been no improvement in spite of medication, vaccine therapy, and surgical treatment.

PROGNOSIS

On account of the satisfactory response to the letters, the bad prognoses formerly given must be reconsidered. With a definite etiologic factor established, it would appear that results should be even better in the future. If the specific therapy of Bergen and Logan continues to be so efficient, it will greatly increase the favorable outlook. Vaccine was tried in Case 2 without much improvement. In Case 7 the response to vaccine therapy was satisfactory. Transfusion in several instances seemed to bring about a change in what appeared to be a progressive downhill course.

TREATMENT

With the establishment of a definite etiology, our main effort must first be to locate and remove

possible foci of infection, second, to treat with a specific vaccine, and third, to improve the child's general, as well as specific, resistance by transfusion.

Residue-producing food may be reduced to a minimum and plenty of carbohydrate given, but, as a rule, the improvement is not very great. The use of large doses of tincture of iodine has produced some striking therapeutic results, but is far from a specific. Kaolin given in large doses of from 15 to 30 grains or more a day seems definitely beneficial, but it is rather difficult for children to take over long periods. Irrigations have not been well tolerated and have been discontinued because no definite benefit has been observed from them. Lastly, if all else fails, an appendicostomy or ileostomy should be performed and the colon put entirely at rest. Unfortunately, even this does not always bring improvement. We are still watching a little patient who had an ileostomy over two years ago and is still in a state of marked emaciation and general weakness.

THE RELATION OF DIET TO THE EYE*

By ARTHUR M. YUDKIN, M. D.,

From the Departments of Surgery, Section of Ophthalmology, and Physiological Chemistry of the Yale University School of Medicine, New Haven, Conn.

THE ophthalmologist has often seen ocular disturbances which were probably due to irregularities in diet. The idea that diseases of the eye may be associated with exceptional dietary conditions is not new. As early as 1835, a condition of hemeralopia or night blindness was found among Russian peasants who observed the customary lenten season. Some investigators also

noted dryness of the conjunctiva and softening of the cornea which was progressive during these fasts. A more aggravated ocular disturbance was found among nurslings who suffered from serious malnutrition because of the religious fasts practiced by the mothers. This condition was not only observed in Russia but a similar ocular manifestation was seen in England among the infants of the poor whose diet was supposed at that time, to lack nitrogenous ingredients. The affection

*Read at the Annual Meeting of the Medical Society of the State of New York, Syracuse, May 12, 1925.

at that time. The same year, following measles, she had had pneumonia, after which there was a bloody dysentery. At times she had passed as much as "a teacup of coagulated blood, just after the feces." There had been from six to eight stools a day, although they were fewer at certain periods. This condition had been almost constant since, except at certain short intervals when the bowels would be very nearly normal.

The general examination was practically negative except that the child was about 8 per cent underweight. The hemoglobin was 61 per cent, and the erythrocytes numbered 3,500,000. The stool showed many erythrocytes and pus, but no parasites. There were no roentgen-ray findings typical of chronic ulcerative colitis. Proctoscopic examination revealed the finely granular condition of the mucosa of the rectum and sigmoid with a few scattered irregular ulcers, and slight contraction of the bowel. The patient was unable to remain for treatment.

Case 7—A boy, aged fifteen, came to the clinic from Wisconsin in February, 1925, complaining of the passage of blood and mucus from the bowels. For the last four or five years he had been subject to spells of diarrhea, accompanied by a certain amount of hemorrhage. These attacks, however, had not been severe enough to interfere with his well-being until a year before, when following an attack of grippe, there was mucus as well as blood in the stools. Saline irrigations followed by starch enemas had helped the condition somewhat. Six months later he was improved, but whenever he discontinued the washings for two or three days the blood would return.

The general physical examination, except for enlarged tonsils 3, with fibrous plugs, was negative. The blood count showed 65 per cent hemoglobin, 4,280,000 erythrocytes, and 8,000 leukocytes. The roentgenogram of the colon was negative. Proctoscopic examination revealed a coarsely granular mucosa of the rectum and sigmoid which bled easily. A diagnosis of granular proctosigmoiditis was made. Cultures from the rectal mucosa showed a pure culture of short-chained streptococcus. The tonsils were removed, and on culture showed streptococci and diplococci. A vaccine was made, and treatment with this for two months has produced considerable improvement. Each time after injecting the autogenous filtrate there has been a slight amount of blood in the stool.

DISCUSSION

This series of cases, added to those already reported, forms a very distinct group, characterized by chronic mucopurulent diarrhea associated with the intermittent or constant presence of blood in the stools.

Etiology—The geographic distribution of the cases, four from Minnesota, one from Wisconsin, one from Nebraska, and one from Oregon, seems to indicate that local conditions do not play a part in etiology. The relationship of parenteral infections to exacerbation has been well recognized, but not until the recent work of Barger has it seemed probable that infection, particularly focal infection, plays a direct part in the etiology of chronic ulcerative colitis. In 80 per cent of his cases he isolated a characteristic diplococcus in cultures made directly from the ulcers. He was unable to isolate the same bacteria from the feces. He has produced experimentally in animals typical lesions in the colon with organisms isolated from foci (teeth, tonsils), as well as from the ulcers, of patients with ulcerative colitis. He has further shown that removal of these foci produced astonishing therapeutic results. The excellent results obtained from transfusions, in the absence of any marked anemia, may readily be explained on the basis of a specific effect of the transfusion on the local infection, such as it has in erysipelas in infants. One child has remained well since the transfusion eighteen months ago. It seems probable, therefore, that chronic ulcerative colitis is a disease that is best explained on the basis of a specific localizing power of an organism. We have for the first time a definite cause for chronic ulcerative colitis, so the term "non-specific ulcerative colitis," as recently used by Lynch and Filsen, can be discarded.

Pathology—As there were no fatalities in this group, nothing new can be added regarding the pathologic changes in the colon. Of special interest is the vascularity of the mucosa, accounting for the large amounts of blood in the stools, and the sclerosis of the muscularis, probably accounting for the absence of haustra and the lead-pipe appearance of the colon in the roentgenogram.

DIAGNOSIS

The diagnosis of chronic ulcerative colitis is based on the persistence of hemorrhagic mucopurulent diarrhea over a long period with intervals of improvement and recurrence. None of the usual etiologic agents—amebae, the bacillus of dysentery or of tuberculosis, or the *Spirochaeta pallida*, is found. The isolation of the diplococcus by Barger seems to point to a definite etiologic factor, contrary to the statement in my first paper. In one patient a single finding of *Entamoeba histolytica* was reported, but in spite of specific treatment for amebae, the condition continued to grow worse. The age of onset was as follows: at four years in one case, at seven years in one, at ten years in four, and at eleven years in one. Three of the seven patients had had symptoms for less than a year, two patients from one to two years, one for five years, and one for seven years. There is a tendency for the diarrhea to show

A slight edema of the eyelids becomes manifest, and the viscid lacrimal secretion assumes a sort of serosanguineous character accumulating in the inner canthi in the form of crusts. The hair of the lids falls out, and the latter become thicker. When the swollen lids, which at this stage may be matted together with a dry secretion, are pushed back, accumulations of semisolid, fat-like, yellowish-white patches of secretion or perhaps exfoliated epithelium in the upper and lower fornices often appear.

In the early stages, the cornea shows no visible changes except for the marked congestion about its junction with the palpebral conjunctiva. With the progress of the eye disturbance and following the swelling of the lids, the cornea shows some signs of haziness particularly about the periphery. As the patches increase, the normal corneal reflexes disappear. Frequently they are seen on the center of the cornea but more often extend on to the corneal surface from the fornices. Thereupon the cornea becomes dry, lusterless and oily in appearance, losing its normal transparency.

In my earlier observations, I thought that the central, fat-like plaques were ulcers, but as the work progressed, it was found that they could be easily removed from the cornea. In order to see how much destruction of the cornea is produced when the plaques are removed, the tissue was stained with fluorescein, to my surprise, it rolled over this area as water does over an oily surface. Seen through a corneal loupe, the tissue seemed to be intact, but a slight swelling in the form of a bleb occupied the areas from which plaques had been previously removed. At such times the animal showed marked debility owing to its nutritional decline. Furthermore, if the experiment was continued, the corneal tissue showed frank ulceration, which stained with fluorescein, and finally, panophthalmitis set in with complete destruction of the eye.

The iris observed in the early stages of the experiment showed very little change, but when the congestion of the conjunctiva was marked, the folds of the iris, observed with a Berger loupe, also became prominent through congestion. Because of the nutritive decline of the animal and the haziness of the cornea at such stages, further accurate observations on the iris became almost impossible.

The pathologic changes in the eyes of experimental animals which were reported were for the most part those which resulted from inflammation and destruction or necrosis of the cornea. With the object of determining the character and site of origin of the initial lesion, and the sequence of changes leading up to the condition of xerophthalmia, a careful histological study was made of the eye and the adjacent structures, including the lids and paraocular glands. These studies, we believe, throw some light on the pathogenesis of

the process, and indicate that the common conception of the eye condition as primarily a lesion of the cornea is incorrect.

In ophthalmia produced in rats by diets deficient in vitamin A, lacrimation is an early symptom, whereas later the secretion decreases with a drying of the conjunctiva. This phenomenon suggested the possibility of an involvement of the paraocular glands in this condition. A second observation that led to investigation of the glands was the fact that the lesions resulting from dietary deficiency generally begin simultaneously in both eyes, with relatively little difference in the rapidity of development on the two sides. Although clinically one eye may appear to be unaffected, microscopic investigation shows that unilateral involvement is exceptional. These considerations indicate that while the character of the eye lesion is essentially that of a bacterial infection of the conjunctiva, there is probably some disturbance outside the eye which makes the infection possible. Since it is known that the lacrimal secretion has bactericidal properties, it seems possible that such a disturbance might lie in the activity of the glands that supply the secretion. A careful histological study of the paraocular glands, therefore appeared warranted. A brief discussion of the anatomy and physiology of these little studied glands may make for clearness.

In the majority of mammals, the conjunctival secretion is supplied for the most part, by two small organs, the lacrimal and the Harderian glands. There are, however, in addition, the Meibomian glands, specialized sebaceous glands which lubricate the margins of the lid, and numerous solitary mucous glands scattered through the conjunctiva of the lids.

In certain species, including the rat and mouse, the lacrimal apparatus consists of two parts, one, intraorbital, the other, extraorbital. The former lies generally behind the eyeball while the latter is found near the angle of the jaw in close relation with the parotid.

The Harderian gland is situated intraorbitally, generally in close apposition to the eyeball. In man, and other primates, it is a small vestigial structure. In the rat, mouse and rabbit, and other animals having a well developed nictitating membrane, or third lid, the gland is quite prominent, and in most of these species is considerably larger than the intraorbital lacrimal, with which, in the rat and mouse, it is closely associated. The amount of gland tissue is proportionately far greater than in man. A histological study shows marked changes in the Harderian gland in this dietary disorder, but little if any in the lacrimal.

I found that if in addition to the lack of vitamin A there is a deficiency of phosphorous or calcium, the ocular disturbance appears earlier in the experiment.

In order to cure the eye disease it is necessary to add the missing "little something" to the diet.

generally attacked both eyes. Keratomalacia was observed in negro children on coffee plantations in Rio de Janeiro where nutritional conditions were said to be poor. By a careful survey of the literature I have encountered numerous references to ocular disturbances in adults confined to prisons, work houses and educational establishments where the food was ordered according to a scheme which today we know is an unbalanced diet.

Of late, the medical profession has recognized the importance of the relation of vitamin deficiency to the general well being of the body. The biochemist has plainly demonstrated by his work in the laboratory, that experimental animals fed on a wholesome diet of protein, carbohydrate, fat and inorganic salts would grow and thrive for a certain length of time, but shortly a multiplicity of lesions would appear. For example, the guinea pig whose diet is made up of oats and cabbage will show a normal growth and health curve, but when the food combination is boiled, scorbutic manifestations may be demonstrated. The bony structure is affected in this deficiency disease. Hemorrhages are found in the periosteal and periodontal tissue and the bone is often very fragile. Hemorrhagic areas have been noted in other parts of the body particularly in the alimentary tract. The joints may be tender and painful. It has been known for many years that certain diets of stale foods produce this very disease among sailors, soldiers and prisoners. It was then noted that if fresh vegetables and fruit were given to these sufferers in the early stages of this disease the pathological conditions disappeared.

Another interesting laboratory experiment is to feed pigeons a diet of highly polished rice whereupon shortly the bird shows progressive weakness followed by convulsive seizures until they die. If the bird is given the bran which has been previously removed from the rice, the pathological condition disappears. This same clinical picture was observed long before the vitamin hypothesis was formulated. In 1884 Admiral Takaki of the Japanese Navy demonstrated during his cruise of about eight months that the peripheral neuritis resulting in paralysis in the disorder known as *beri-beri* had developed because of a faulty diet which his sailors were fed. Scurvy was found to be prevalent among the sailors in the early days of navigation. It is said that Jacques Cartier in 1536 lost some twenty-six of his party from scurvy.

Precisely the same sort of an experience was noted during the great war in several of the fields of operation. In the far east during the siege of Kut, the English soldiers at the front developed scurvy and the Indian troops with the British developed *beri-beri*. Martin tells the story of the African soldiers who were with a British unit in France and were fed the same ration as the British. The latter soldiers seemed

to thrive and showed no manifestations of scurvy whereas the former suffered immensely from this malady. In order to cure them of this pitiful condition they were denied fire wood for cooking their food and shortly scurvy disappeared.

I have cited briefly a few incidents in which different members of the body may show pathological disturbance due to the lack of some little thing in the food even though the diet was made up of the proper amounts of protein, carbohydrates, fat and inorganic salts. Poverty of certain rations in phosphorus, calcium and other inorganic nutrients may give rise to definite pathological changes in the animal body. McCollum and his co-workers have recently discovered that certain experimental animals develop a type of ophthalmia due to the lack of some inorganic substances. It has also been shown that the incidence of goiter grows with the lack of iodine associated with increasing distance from the sea, so that the region of the Great Lakes is quite goitrous.

With the aid of animal experimentation the biochemist has blazed the trail into the unexplored regions of dietics so that the clinical investigators may travel with greater certainty. The reasons for it is that today we are able to control our results more accurately and in that way study the pathological aspect of the ailment in its different forms. The newer ideas of nutrition clearly demonstrate that laboratory animals fed a mixture of purified proteins, carbohydrates, fats and artificial inorganic salts require vitamins for normal growth and health. With this present knowledge it is possible to vary the amounts of ingredients so that several combinations of diets may be used.

It was by this method of systematic investigations of diet on the albino rat that my attention was called to the lesions of xerosis of the conjunctiva and keratomalacia. This ocular manifestation was found by laboratory workers, notably Osborne and Mendel who tried to alleviate this eye disease with ocular medicaments but it was obdurate to general treatment. With the finding of the cause of this disturbance the condition cleared up like magic by the addition of the missing dietary factor. To illustrate this more specifically let us follow the clinical course of the ocular disturbance.

When animals are on a diet devoid of vitamin A for some time the first sign of an ocular complication is that the eyes water very freely, and the animals seem to dread the light more than a normal individual does. The normally prominent protruding eye of the rat gradually recedes into its bony orbital socket, and the photophobia increases. The animal facies assumes a sleepy appearance. Lacrimation increases and, instead of being watery, becomes more viscid. It is at this stage that the animal shows some signs of ocular irritation and rubs the lids with its front paws.

ease and from all outward appearance seemed to be a slight cold but disappeared when the infants general health improved?

In this era of preventive medicine, it is just as important that the infant have a well balanced diet with the proper amount of vitamins as it is to place silver nitrate in the conjunctival sac of the new born as a precautionary measure against gonorrheal ophthalmia. It is just as important to see that the child receives a wholesome diet rich in fresh milk, butter, vegetables and cod liver oil during the period of diminished resistance and vitality, particularly after an attack of the measles, whooping cough, scarlet fever and other

prevalent children diseases. Our American ophthalmologist like our clinicians have been inclined to minimize its practical significance because of the rarity of reports of human cases which have appeared in this country and that the malady is only of an academic interest rather than a serious medical problem. The unfortunate experiences of Europe with its less favorable economic conditions and food problems, where the disorder in question has been seen in great numbers, should make us physicians in America better prepared to recognize xerophthalmia, to understand its origin and to treat, or better still, avert it.

CONSERVATISM IN THE TREATMENT OF ECLAMPSIA

By HERVEY C WILLIAMSON, M D

NEW YORK CITY

THE treatment of eclampsia has passed through several definite epochs. First, a radical period, when immediate delivery was considered the crux of the treatment. This treatment was based on the theory that fetal and placental metabolism was an etiological factor. The technique of cesarean section had not been perfected while this method was in vogue, so accouchement forcé was practised. Manual dilatation followed by forceps or version was done. As, under this plan, there was an extremely high mortality from shock, hemorrhage, and sepsis, it was gradually abandoned. The second era might be called moderately conservative. The idea still persisted that delivery was essential in the treatment and this was accomplished by use of the hydrostatic bag followed by spontaneous or less traumatic operative delivery. The present tendency is toward pure conservatism in the treatment of this disorder.

Let us consider the rationale of this treatment. For fifteen years, Strogonoff has practised this type of treatment with astonishing results. His mortality figures are so much lower than those from other clinics that they should be considered seriously. Last year, Stander visited Leningrad and was allowed to investigate thoroughly Strogonoff's records. He found that there had been 390 cases of eclampsia in two clinics over a period of fifteen years, with but 30 deaths, a gross mortality of 7.7 per cent. Strogonoff's recent statistics are lower, which he attributes to a more rigid adherence to the technique than in the earlier years. Stander concludes, in part, that 70 per cent of Strogonoff's patients had no convulsions before admission to the clinic and 50 per cent of these had only one convulsion—obviously mild seizures. Furthermore, he finds that two-thirds

of Strogonoff's maternal mortality occurred in patients who had had four or more convulsions before admission to the clinic. From 1916 to 1924, among women who had convulsions before admission to the clinic, the mortality was 9.3 per cent. Possibly some of Strogonoff's records should not be accepted, as he includes several patients who had convulsions ten or more days post partum and probably some others who had chronic nephritis with convulsions.

Wilson, in a recent paper, reports a 50 per cent reduction in the maternal mortality of ante and intrapartum eclampsia under conservative treatment at the Johns Hopkins Hospital.

As long as the etiology of eclampsia is obscure there will be variations of opinion as to its treatment. However, there now seems to be a unanimity of opinion in favor of conservatism though the methods of necessity must be empirical. Notwithstanding the criticism of Strogonoff's statistics we decided, in 1923, to adopt his method with slight variations.

On the Second Obstetrical Division at Bellevue Hospital the following instructions are given to the Resident Obstetrician.

TREATMENT

- 1 Prophylaxis (a) Antenatal care.
(b) Induction when high blood pressure and albuminuria persist and eye symptoms are severe.
- 2 Hospitalization.
- 3 Minimum obstetrical interference.
- 4 Medical treatment.

After Convulsions Have Occurred

- 1 Isolation.
- 2 Attention to the respiratory passages.
- 3 Morphine Sulph. 0.15 gm ($\frac{1}{4}$ gr) at once.
- 4 Secure specimens (1) Urine (2) Blood. (3) B. P. observations (4) Obstetrical examination (5) Eye examination.

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse May 13, 1925.

The animal is given 5 drops of cod liver oil daily but more accurate work has shown that only one milligram or 1/50 of a drop of good cod liver oil per day will cure the ocular disturbance and stimulate growth in rats

There are several instances of the occurrence of conditions described in the literature as xerophthalmia and keratomalacia which seem to be beyond question, cases in which the disease has occurred in man as the result of specific starvation for the dietary essential vitamin A. The records particularly referred to are those of Block. He tells a most interesting story of how the children of Denmark, particularly those of the poor, suffered from this ocular disturbance which was due to the fact that the Danes sold their dairy products to the warring nations and used margarine as a substitute. He has investigated over seventy cases of this eye disturbance. Most of these were under his personal supervision for a long period of time before the xerophthalmia occurred. It was impossible to explain the presence of the disturbance in all the cases on the score of deficiency of vitamin A in the diet alone. For a good portion of the children received some of the essential factor even though the amount of fresh milk was small or it was stale at times or pasteurized and diluted half or more with water and boiled with flour to make gruel. He concluded that xerophthalmia may arise partly because of the deficient supply of vitamin A, due to lack of the essential in the food or the accompanying disease conditions of the digestive tract which hinders assimilation of this factor and partly from decreased consumption of vitamin A during periods of growth and in chronic wasting diseases. Yet Stransky has reported xerophthalmia in four cases which did not improve with the addition of vitamin. It is possible that these children consumed considerable of the essential and could not absorb it and therefore passed through the alimentary tract unused. The administration of the vitamin A by some other route must be used.

Blegvad, who made a careful survey of the cases found in Denmark has given subcutaneous injection of a concentrated cod liver oil preparation. The xerosis disappeared as a result of this injection. In five cases of xerophthalmia Block injected the ordinary cod liver oil which was sterilized in boiling water. It was previously sealed in glass tubes to as to prevent the access of air. For the first injection 0.5 cc was given and then 1 cc daily for the first four to eight days. The cod liver oil injections were painless and there was no reaction at the site of inoculation for the first few days. After from four to eight days, a rather large infiltration always appeared with redness and tenderness at the site of inoculation attended by indisposition and intermittent fever, the evening temperature being between 38°-39° C. This lasted almost a week, but the

tenderness persisted for several weeks afterwards and the infiltration disappeared little by little. In spite of these inconveniences he considers the advantages are so great that we ought to give cod liver oil injections to every patient in whom the cornea is attacked. To insure against idiosyncrasy a small dose should be given first. This method was adopted because of the experimental evidence that B and C factors can be absorbed when injected subcutaneously and intravenously.

From many quarters of the world numerous cases of hemeralopia or night blindness have been reported. Accompanying the descriptions of this disorder there is a history of faulty nutrition. Fernando describes a condition of night blindness found in the Philippines which occurs without xerosis of the conjunctiva. Epidemic night blindness is observed in settlement houses, orphanages, and other places where poor diet is usually served. In cases of beri-beri of the rudimentary type hemeralopia was the most prominent complaint. Elliot states that there is no necessary relation ship between xerosis of the conjunctiva and night blindness which they encounter in the tropics. The condition disappears with the ordinary treatment of beri-beri. Little reports the prevalence of night blindness among the people of Newfoundland. The diet of the inhabitants of this northern climate is probably low in vitamin A as well as deficient in other respects so that either beri-beri or scurvy would give them this ocular manifestation.

In Japan where there is no dairy industry, the supply of vitamin A must come from other sources. The inhabitants along the coast where fish is plentiful do not suffer from this malady. Mori has described a children's disease occurring in Japan during the summer months as Hikan, which is identical with the ophthalmia of Brazil and the xerosis of the conjunctiva and cornea seen in Russia during the lenten fasts. The children suffered from diarrhea in addition to the xerosis of the conjunctiva and keratomalacia. The eye symptoms were relieved by chicken livers, eel fat and cod liver oil—food products which we know today contain vitamin A. Following the earthquake in Japan it was reported that several hundred school children in Tokio suffered from this same disturbance.

It so happens that in America where this problem of xerophthalmia has been studied from every possible experimental angle, the condition of living has been good and the human clinical picture of this disease is therefore rare. Yet I venture to say if a census of the blind in this country were taken we would find many cases in which blindness came on in the early part of the child's life, due to improper feeding. The general practitioner and pediatrician can probably add a few more cases to the list that have not been reported. How many of you have seen cases of malnutrition which were accompanied by eye dis-

justifiable. If a patient recovers from the seizures and symptoms such as hemorrhage develop, labor should be induced. We also believe that in a patient who has recovered and who has a living full term child, labor may be safely induced by castor oil and quinine or by the use of a bag. We have considered rupturing the membranes when an eclamptic patient enters the hospital but have decided, for the present, to adhere closely to our modified plan.

SUMMARY

While the number of eclampsia cases reported is small, our results have been better since we

have adopted this definite medical plan of treatment. We wish to emphasize the fact that there should be no obstetrical interference during the seizure. Obviously a case of intrapartum eclampsia with dystocia must be treated as is any other such case. Induction after the attack has been alleviated may be used for intra-uterine fetal death or for a living full term pregnancy. The time element for the administration of morphine and chloral is, we believe, important. Lastly the value of venesection should not be overlooked.

THE INTRAVENOUS USE OF PARALDEHYDE IN ECLAMPSIA

By WILLIAM EDGAR CALDWELL, M D

NEW YORK CITY

A DRUG which will immediately control convulsions and delirium is of great value in obstetrical practice. For instance, in status epilepticus during pregnancy, in serious cases of chorea, in maniacal stages of puerperal insanity, but especially in the toxemias of pregnancy, with eclampsia. In recent years more and more emphasis has been placed on the effect on the nervous system of the toxemias of pregnancy. Great efforts are made to prevent the exhaustion of the woman by the nervous excitement, allowing time for the elimination of the toxins. The patients are handled as little as possible. No longer are we operating on patients during the height of their attack. The least manipulation possible in the care of the patient has given the best result. Morphine has proved invaluable and has greatly reduced the mortality in such cases. Immense doses have frequently been given. Morphine frequently causes a primary excitement stage and also causes vomiting, thus increasing the danger of asphyxia. Hyoscin and scopolamine have been used with good effect, but they are both dangerous cardiorespiratory depressants. The use of chloroform, as advocated by Stroganoff for controlling convulsions and preventing nervous irritation during necessary manipulations, is not entirely satisfactory and frequently is dangerous. Ether, with its primary excitement stage, has also proved unsatisfactory. Tweedy has called attention in his various articles to the dangers of medication by mouth, the drug not being absorbed and the ingestion of anything into the stomach increasing the dangers of asphyxia from vomiting. Rectal medications in such conditions are slow and uncertain in action. We learned from Dr. Walter Palmer that, both as an interne, and while on the Attending Staff at the Massachusetts General Hospital, and afterward at the

Presbyterian Hospital, he had used paraldehyde in 1 cc. to 3 cc. doses, directly into the vein, with very satisfactory results and no accidents. Very little could be found in the literature on the intravenous use of paraldehyde.

The credit for being the first to use paraldehyde into the vein was claimed by Noel and Soutter in 1912. They gave 15 cc. of paraldehyde in 15 cc. of ether with 15 cc. of 1% cold saline solution directly into the vein. Within 40 seconds of starting such an infusion the patients were asleep, and within 90 seconds the corneal reflexes were gone, allowing them to do short operations. The effect of the drug began to disappear as soon as the infusion was finished. The patients had a short, deep sleep, from which they could easily be aroused and the relaxation continued for several hours. They reported no after effects from the use of the drug in this manner.

Atkey in 1913 gave 5 cc. of paraldehyde in 150 cc. of saline solution to control the convulsions of tetanus, repeating it several times with good results. The patient ultimately recovered.

Homan and Hassler also in 1913 reported the use of paraldehyde in 2½ and 3% solution, both alone and with ether. These same authors in Gwathney's "Anesthesia," 1924, call attention to the crenation of the red blood cells, following the use of paraldehyde and ether in large doses, but claim that the cells returned to normal within 4 hours.

Collier reported 7 cases in 1914 and Cale reported in the same year 6 cases in which 5 to 15 cc. of paraldehyde was given intravenously. All these authors call attention to the danger of using warm saline unless it is well and constantly shaken, as paraldehyde gathers at the top of the solution.

Both Dr. Chas. C. Lieb, Professor of Pharma-

- 5 (a) If not in coma, castor oil 64 cc. (2 oz)
(b) If in coma, gastric lavage. Leave in magnesium sulph 64 cc. (2 oz) saturated solution
- 6 Colonic irrigation every 6 hours
- 7 Chloral hydrate 2 gm (30 gr) in 100 cc. of water by rectum 1st hour
- 8 If convulsions occur and blood pressure is over 200, venesection 500 to 800 cc
- 9 Morphine Sulph 0.15 gm ($\frac{1}{4}$ gr) 3rd hour
- 10 Chloral Hydrate 2 gm (30 gr) 7th hour unless in coma
- 11 Chloral Hydrate 15 gm (22 gr) Unless in coma and there has been an absence of convulsions since admission 13th hour
- 12 Chloral Hydrate 15 gm (22 gr) 20th hour With individualization.
- 13 Terminate the labor when the second stage has occurred
- 14 No food for 24 hours Water if the patient is conscious
- 15 Milk 25 oz on second day
- 16 Carbohydrate diet afterwards.
- 17 Do not breast feed the infant the first 5 days

Our treatment differs from the original in the following points We have not given chloroform for the examination, nor have we given oxygen after a convulsion We perform venesection for high blood pressure, whereas Stroganoff removes 400 cc. of blood after the third convulsion As we have found the colonic irrigations, not called for in the original, to be disturbing and possibly harmful to the edematous patients, they have been omitted We do nothing to institute labor in the antepartum cases

Our total number of patients so treated is small but we wish to contrast some of the recent results with those of a former year when moderately conservative methods were used On our service at Bellevue Hospital (6 months per year), in 1922 there were 15 eclamptic patients with 6 maternal deaths, 6 stillbirths, and one neonatal death

15 CASES OF ECLAMPSIA—1922

Ante and Intrapartum Treatment	Maternal Deaths	Stillbirths	Neonatal Deaths
Hydrostatic bag	7	3	1
Forceps deliveries	2	0	0
Undelivered	1	1	0
	10	4	1
Postpartum			
Spont. delivery	4	2	0
Cramotomy	1	0	0
	5	2	0

The Ante and Intrapartum Deaths Were as Follows

1 Para iii 3 convulsions at home. Treated by hydrostatic bag Spontaneous delivery Living baby 7 postpartum convulsions Death 3 days postpartum.

2 Para v One convulsion in hospital. Hydrostatic bag inserted. Expelled in 12 hours 120 mm drop in blood pressure with sudden death. Stillborn baby delivered at time of death.

3 Para i Admitted in coma. 6 months pregnant. 6 convulsions before admission to the hospital. 8 in the hospital Died undelivered 10½ hours after admission.

4 Para i Admitted in coma. 4 convulsions at home. Hydrostatic bag introduced Macerated stillbirth. Re-

tained placenta removed 16 hours later Patient remained in coma and died

The Postpartum Deaths Were as Follows

1 Para ii Admitted in coma. Twins delivered at home. 3 convulsions at home, 6 in the hospital

2 Para vii Delivered premature twins 7 postpartum convulsions

During 1923, 1924, and so far in 1925 there have been 16 eclamptic patients with one maternal death, 6 stillbirths, and 3 neonatal deaths All of these cases have had the medical treatment without obstetrical interference.

14 CASES OF ECLAMPSIA—1923, 1924 1925

	Number of Cases Antepartum	Postpartum	Maternal Deaths	Still Births	Neonatal Deaths
1923	4	0	0	2	1
1924	7	1	0	3	1
1925	3	1	1	1	1
	14	2	1	6	3

The maternal death occurred in 1925 Patient a para ii, 28 years old In coma on admission. No history as to the number of convulsions at home obtainable 3 convulsions in the hospital Routine treatment begun Pulmonary edema developed and patient died about 6 hours after admission

The essential difference between the treatment in 1922 and that of subsequent years is that we have stopped the induction of labor during the seizure. In 1923, the routine as outlined was begun Before the routine was adopted larger amounts of morphine were given than we now use Chloral was not given

The termination of pregnancy of the antepartum cases under the conservative treatment is interesting Two patients went into spontaneous labor on the second and fourth days after admission for convulsions, the first delivered a living baby, the second a six months macerated fetus In two patients the membranes were ruptured artificially on the fifth and sixth days after the seizures and macerated fetuses were delivered One patient passed eighteen days in the ward after the seizures and during this time she had a high blood pressure with albumin in the urine but no further convulsions On the nineteenth day she passed a large blood clot, labor was induced by stretching the cervix, castor oil and quinine were given, and a dead baby was spontaneously delivered The fetal heart had been heard, however, in the early stage of labor In another patient a bag was inserted three days after the seizures A living and apparently normal baby was delivered spontaneously but died of cerebral hemorrhage on the third day

We are in a somewhat anomalous position regarding the induction of labor, advocating it for severe pre-eclampsia but not after a convulsion has occurred We feel that after a patient has been relieved of the convulsions and fetal death has occurred, induction by rupture of the membranes is

THYROID FEEDING IN PITUITARY DISEASE

By F W MARLOW, M D
SYRACUSE, N Y

IN the Archives of Ophthalmology for March, 1917, Elsberg and Krug say, "In spite of the advances that have been made in the knowledge of pituitary disease, the results of surgical treatment must, in the main, be considered unsatisfactory."

Blair Bell in his work "The Pituitary" 1919 referring to the results of different operations collected by Cope says, "One fact stands out clearly, however, and that is that up to the present time the benefit derived from operation has rarely been permanent."

At an earlier date Fisher in the Transactions of the Ophthalmological Society of the United Kingdom for 1911, is still more emphatic, saying of operative treatment that, "The difficulties are enormous and the results deplorable."

Just to what extent the two more recent quotations may be taken to indicate an improvement in the surgical situation, I do not know, but it seems obvious that the prospect of permanent relief by surgical interference is not great enough to justify a resort to it, until all other possibilities have been exhausted. Presumably there are cases in which the pathological changes are of such a nature as to make any other form of treatment of no avail, and others in which antisiphilitic, glandular, radium and x-ray treatment have proved valueless, the only remaining alternatives being operation or nothing, but as De Schweinitz points out in his Bowman lecture, "Anyone can readily convince himself by an examination of the literature of this subject, that evidence, apparently trustworthy, of the value of glandular feeding is abundant not only in relation to the relief of pituitary headaches, but also, sometimes in a startling manner, where the indications of gross hypophyseal disorder (adenoma, etc.) were present." In spite of this abundance of apparently trustworthy evidence of the value of glandular feeding in these cases, there is no reference to it in the recent edition of Hare's Therapeutics, a very brief reference to it in the last edition of Sajous' Cyclopaedia, and in Blair Bell's book a single statement, that it is sometimes of use in cases of Hyperpituitism, especially cases of arrested acromegaly.

The title of the present paper is a little misleading as it is intended to refer only to the effect of Thyroid feeding on the visual symptoms of Pituitary disease, and the excuse for the paper itself is that I find among my records notes, quite brief for the most part, of five cases of pituitary disease in which thyroid extract was administered.

Before reading the notes, of these cases, it may be of interest to review very briefly some of the cases which have already been put on record in which thyroid extract has been used.

I think that my attention was first called to the subject by a paper by J H Fisher in the Ophthalmic Review for 1908, in which marked benefit both in visual acuity and in the field of vision followed the administration of thyroid extract. Commenting on this case he says that "It appears to show that thyroid extract alone is an adequate remedy for some forms of pituitary hypertrophy, and that the products of the pituitary body and thymus glands are in some cases at least superfluous" and, that administration of thyroid products will supply the economy with something which the pituitary gland by excessive effort is endeavouring to provide," appears to be a simple explanation of the good effect of this treatment.

In a paper published in the Transaction of the English Ophthalmological Society in 1911, the same author reports nine cases of Pituitary disease in four of which the effect of thyroid feeding alone is noted. In two of these cases no improvement took place. In one V rose in the better eye from 6/24 to 6/9— The other eye was blind and remained so. In one case V grew rapidly worse with the other symptoms. In the discussion on this paper Lawford contributes a case of pituitary disease in which remarkable improvement in vision of one eye, from 6/24 to 6/6 with large gain in the temporal field, followed the administration of thyroid extract. In the other eye atrophy of the optic nerve was too far advanced for recovery to be possible.

De Schweinitz in his Bowman lecture refers to the case of a woman aged 39, with symptoms of hypopituitarism whose visual symptoms "Progressed from the stage of paracentral scotoma, through that of advancing bitemporal hemianopia to complete loss of light perception lasting twelve days in the right eye and six weeks in the left." For ten months she took thyroid extract, apparently about 16 grains daily, and recovered normal direct and indirect vision. Four years later she had a relapse chiefly of the left eye and a year later a second relapse. Cure again followed thyroid extract therapy.

Cummins in the British Journal of Ophthalmology for 1923 reports the case of a woman aged 33, in which V was reduced to 1/60 in the right and 6/18 in the left eye. One grain of thyroid extract was administered daily by mouth. There was a rapid improvement both in vision and fields in nine days and finally full vision and normal fields in each eye.

Eason also has described a case of a patient practically blind who recovered normal vision and nearly a full field in one eye after thyroid feeding. The improvement had persisted for nine years. The patient had to take small doses of

cology in Columbia University, and Dr George Wallace, Professor of Pharmacology in New York University, consider it safe to use small doses of paraldehyde intravenously if given very slowly and carefully. The dangers they call attention to are cardio-vascular depression and especially respiratory failure following large doses.

Paraldehyde ($C_6H_{12}O_3$) is a polymer of ethylaldehyde. It is a colorless liquid of pungent odor, soluble in 85 parts of water, and freely soluble in alcohol and ether. It is antiseptic. Internally, it resembles the action of alcohol, but it is a much more powerful hypnotic and seldom causes excitement. It has not the effect upon the protein metabolism as has been observed after the prolonged administration of chloral. The danger involved in the use of paraldehyde is that, in large doses, it is liable to paralyze the respiratory center. It does not affect the heart directly. By its action on the nervous system it quickly induces sleep, which lasts several hours. The sleep is quiet, refreshing and dreamless and leaves no bad after effects. Paraldehyde is excreted very rapidly by the lungs and especially by the kidneys. Some authors claim that it is difficult to give an overdose, since the excretion is so rapid. As much as 3 ounces have been given with no bad results.

In May, 1922, we reported to the New York Obstetrical Society the intravenous use of paraldehyde in 15 cases. This was published in the *American Journal of Obstetrics and Gynecology*, September, 1922. Since that time we have used it in 32 additional cases, making 47 cases in all. In the original report the average dose was 1 cc of U S P paraldehyde given directly into the vein. The effect in the majority of cases was startling, the patient relaxed immediately and went into a natural sleep, the respirations became deeper and more regular, the cyanosis cleared up and the blood pressure sometimes dropped from 15 to 20 mercury mm and the pulse became full, regular and much slower. With added experience we have increased the dosage until now we give an average of 2 cc, occasionally as much as 3 cc directly into the median-basilic vein. With these small doses the anesthetic action is very short, but it is sufficient to allow the careful examination of the patient and to make such necessary manipulations as phlebotomy, washing out of the stomach and the rectum without disturbance to or excitement of the patient. The anesthetic action is followed by a considerable period of relaxation and allows time to obtain the physiological action of morphine administered at the same time as the paraldehyde injection. In eclampsics we always give $\frac{1}{4}$ to $\frac{1}{2}$ gr of morphine and repeat with smaller doses until a physiological reaction of the drug is obtained. In over 60% of our cases there have

been no further convulsions after the initial dose. When convulsions do recur we have not hesitated to give a second injection of paraldehyde. In one case $7\frac{1}{2}$ cc were given within the first 24 hours and a total of 13 cc during the first three days. This woman ultimately recovered and the baby was born alive, a forceps operation being necessary after the acute attack had been controlled. We have also used paraldehyde by rectum in $\frac{1}{2}$ to 1 ounce doses, always mixed in oil. This dosage has given the patients a quiet sleep and reduced the amount of morphine necessary. In one case of difficult labor, instead of using ether, as Gwathney recommends, we used paraldehyde, $1\frac{1}{2}$ oz of the paraldehyde being given instead of ether. This woman slept soundly for 14 hours, arousing slightly during the uterine contractions, which apparently were not affected in the slightest degree by the drug. A difficult forceps was necessary for the delivery after full dilatation of the cervix. In her previous labor the same operation had been necessary. In this case we had difficulty in resuscitating the baby and it died the following day. The baby's breath smelled very strongly of paraldehyde and whether the death resulted from the effects of the drug or from a birth injury we are uncertain, as autopsy was refused. In the cases where we have used the paraldehyde intravenously we have noticed no bad effects either on the mother or the child.

Paraldehyde is not used for its curative effects in toxemias of pregnancy, but merely as an aid in controlling the patient while other means for relief of the condition are being instituted. And using it in this manner we have been well pleased with the results obtained and have had no accidents.

SUMMARY

- 1 Paraldehyde, either undiluted or diluted with saline solution, can be given very slowly into a vein in small doses with apparent safety.

- 2 Its action produces a deep sleep in less than one minute, relaxing the muscles, thus preventing exhaustion due to muscular contractions while other means are being used to eliminate the toxins, or while waiting for the physiological effect of morphine.

- 3 Its hypnotic effect is of short duration, from one hour to one hour and a half.

- 4 It is much more satisfactory than chloroform or ether for the immediate control of convulsions and delirium.

- 5 Since the hypnotic effect is followed by muscular relaxation lasting for several hours, less morphine is required than would otherwise be necessary.

- 6 The results thus far obtained, both by ourselves and others, fully warrant the further trial of paraldehyde, although a drug so powerful in its action should be used only with the utmost care.

THYROID FEEDING IN PITUITARY DISEASE

By F W MARLOW, M D
SYRACUSE, N Y

IN the Archives of Ophthalmology for March, 1917, Elsberg and Krug say, "In spite of the advances that have been made in the knowledge of pituitary disease, the results of surgical treatment must, in the main, be considered unsatisfactory."

Blair Bell in his work "The Pituitary" 1919 referring to the results of different operations collected by Cope says, "One fact stands out clearly, however, and that is that up to the present time the benefit derived from operation has rarely been permanent."

At an earlier date Fisher in the Transactions of the Ophthalmological Society of the United Kingdom for 1911, is still more emphatic, saying of operative treatment that, "The difficulties are enormous and the results deplorable."

Just to what extent the two more recent quotations may be taken to indicate an improvement in the surgical situation, I do not know, but it seems obvious that the prospect of permanent relief by surgical interference is not great enough to justify a resort to it, until all other possibilities have been exhausted. Presumably there are cases in which the pathological changes are of such a nature as to make any other form of treatment of no avail, and others in which antisiphilitic, glandular, radium and x-ray treatment have proved valueless, the only remaining alternatives being operation or nothing, but as De Schweinitz points out in his Bowman lecture, "Anyone can readily convince himself by an examination of the literature of this subject, that evidence, apparently trustworthy, of the value of glandular feeding is abundant not only in relation to the relief of pituitary headaches, but also, sometimes in a startling manner, where the indications of gross hypophyseal disorder (adenoma, etc.) were present." In spite of this abundance of apparently trustworthy evidence of the value of glandular feeding in these cases, there is no reference to it in the recent edition of Hare's Therapeutics, a very brief reference to it in the last edition of Sajous' Cyclopedia, and in Blair Bell's book a single statement, that it is sometimes of use in cases of Hyperpituitism, especially cases of arrested acromegaly.

The title of the present paper is a little misleading as it is intended to refer only to the effect of Thyroid feeding on the visual symptoms of Pituitary disease, and the excuse for the paper itself is that I find among my records notes, quite brief for the most part, of five cases of pituitary disease in which thyroid extract was administered.

Before reading the notes, of these cases, it may be of interest to review very briefly some of the cases which have already been put on record in which thyroid extract has been used.

I think that my attention was first called to the subject by a paper by J H Fisher in the Ophthalmic Review for 1908, in which marked benefit both in visual acuity and in the field of vision followed the administration of thyroid extract. Commenting on this case he says that "It appears to show that thyroid extract alone is an adequate remedy for some forms of pituitary hypertrophy, and that the products of the pituitary body and thymus glands are in some cases at least superfluous" and, that administration of thyroid products will supply the economy with something which the pituitary gland by excessive effort is endeavouring to provide," appears to be a simple explanation of the good effect of this treatment.

In a paper published in the Transaction of the English Ophthalmological Society in 1911, the same author reports nine cases of Pituitary disease in four of which the effect of thyroid feeding alone is noted. In two of these cases no improvement took place. In one V rose in the better eye from 6/24 to 6/9— The other eye was blind and remained so. In one case V grew rapidly worse with the other symptoms. In the discussion on this paper Lawford contributes a case of pituitary disease in which remarkable improvement in vision of one eye, from 6/24 to 6/6 with large gain in the temporal field, followed the administration of thyroid extract. In the other eye atrophy of the optic nerve was too far advanced for recovery to be possible.

De Schweinitz in his Bowman lecture refers to the case of a woman aged 39, with symptoms of hypopituitarism whose visual symptoms "Progressed from the stage of paracentral scotoma, through that of advancing bitemporal hemianopia to complete loss of light perception lasting twelve days in the right eye and six weeks in the left." For ten months she took thyroid extract, apparently about 16 grains daily, and recovered normal direct and indirect vision. Four years later she had a relapse chiefly of the left eye and a year later a second relapse. Cure again followed thyroid extract therapy.

Cummins in the British Journal of Ophthalmology for 1923 reports the case of a woman aged 33, in which V was reduced to 1/60 in the right and 6/18 in the left eye. One grain of thyroid extract was administered daily by mouth. There was a rapid improvement both in vision and fields in nine days and finally full vision and normal fields in each eye.

Eason also has described a case of a patient practically blind who recovered normal vision and nearly a full field in one eye after thyroid feeding. The improvement had persisted for nine years. The patient had to take small doses of

cology in Columbia University, and Dr George Wallace, Professor of Pharmacology in New York University, consider it safe to use small doses of paraldehyde intravenously if given very slowly and carefully. The dangers they call attention to are cardio-vascular depression and especially respiratory failure following large doses.

Paraldehyde ($C_6H_{12}O_3$) is a polymer of ethylaldehyde. It is a colorless liquid of pungent odor, soluble in 85 parts of water, and freely soluble in alcohol and ether. It is antiseptic. Internally, it resembles the action of alcohol, but it is a much more powerful hypnotic and seldom causes excitement. It has not the effect upon the protein metabolism as has been observed after the prolonged administration of chloral. The danger involved in the use of paraldehyde is that, in large doses, it is liable to paralyze the respiratory center. It does not affect the heart directly. By its action on the nervous system it quickly induces sleep, which lasts several hours. The sleep is quiet, refreshing and dreamless and leaves no bad after effects. Paraldehyde is excreted very rapidly by the lungs and especially by the kidneys. Some authors claim that it is difficult to give an overdose, since the excretion is so rapid. As much as 3 ounces have been given with no bad results.

In May, 1922, we reported to the New York Obstetrical Society the intravenous use of paraldehyde in 15 cases. This was published in the *American Journal of Obstetrics and Gynecology*, September, 1922. Since that time we have used it in 32 additional cases, making 47 cases in all. In the original report the average dose was 1 cc of U S P paraldehyde given directly into the vein. The effect in the majority of cases was startling, the patient relaxed immediately and went into a natural sleep, the respirations became deeper and more regular, the cyanosis cleared up and the blood pressure sometimes dropped from 15 to 20 mercury mm and the pulse became full, regular and much slower. With added experience we have increased the dosage until now we give an average of 2 cc, occasionally as much as 3 cc directly into the median-basilic vein. With these small doses the anesthetic action is very short, but it is sufficient to allow the careful examination of the patient and to make such necessary manipulations as phlebotomy, washing out of the stomach and the rectum without disturbance to or excitement of the patient. The anesthetic action is followed by a considerable period of relaxation and allows time to obtain the physiological action of morphine administered at the same time as the paraldehyde injection. In eclampsics we always give $\frac{1}{4}$ to $\frac{1}{2}$ gr of morphine and repeat will smaller doses until a physiological reaction of the drug is obtained. In over 60% of our cases there have

been no further convulsions after the initial dose. When convulsions do recur we have not hesitated to give a second injection of paraldehyde. In one case $7\frac{1}{2}$ cc were given within the first 24 hours and a total of 13 cc during the first three days. This woman ultimately recovered and the baby was born alive, a forceps operation being necessary after the acute attack had been controlled. We have also used paraldehyde by rectum in $\frac{1}{2}$ to 1 ounce doses, always mixed in oil. This dosage has given the patients a quiet sleep and reduced the amount of morphine necessary. In one case of difficult labor, instead of using ether, as Gwathney recommends, we used paraldehyde, $1\frac{1}{2}$ oz of the paraldehyde being given instead of ether. This woman slept soundly for 14 hours, arousing slightly during the uterine contractions, which apparently were not affected in the slightest degree by the drug. A difficult forceps was necessary for the delivery after full dilatation of the cervix. In her previous labor the same operation had been necessary. In this case we had difficulty in resuscitating the baby and it died the following day. The baby's breath smelled very strongly of paraldehyde and whether the death resulted from the effects of the drug or from a birth injury we are uncertain, as autopsy was refused. In the cases where we have used the paraldehyde intravenously we have noticed no bad effects either on the mother or the child.

Paraldehyde is not used for its curative effects in toxemias of pregnancy, but merely as an aid in controlling the patient while other means for relief of the condition are being instituted. And using it in this manner we have been well pleased with the results obtained and have had no accidents.

SUMMARY

- 1 Paraldehyde, either undiluted or diluted with saline solution, can be given very slowly into a vein in small doses with apparent safety.
- 2 Its action produces a deep sleep in less than one minute, relaxing the muscles, thus preventing exhaustion due to muscular contractions while other means are being used to eliminate the toxins, or while waiting for the physiological effect of morphine.
- 3 Its hypnotic effect is of short duration, from one hour to one hour and a half.
- 4 It is much more satisfactory than chloroform or ether for the immediate control of convulsions and delirium.
- 5 Since the hypnotic effect is followed by muscular relaxation lasting for several hours, less morphine is required than would otherwise be necessary.
- 6 The results thus far obtained, both by ourselves and others, fully warrant the further trial of paraldehyde, although a drug so powerful in its action should be used only with the utmost care.

was pale. In other respects, including an x-ray examination of the skull, examination was negative. Thyroid exact in one grain doses, after each meal was ordered.

She was seen again six weeks later when she said that she was better in every way. The night sweats had ceased and the bloating gone out of her hands. Test of the visual acuity gave the R eye 6/18+, and the L 6/60, but she was emphatic in the statement that she saw much better.

After this visit she passed completely from observation.

Case 4

Case 4—Sister J., age 55, first seen November 15, 1915. She then stated that the outer half of her left eye had been quite blurry for two months, and that for the past month she had been unable to see when she looked down.

Her vision was R 6/36 improved by refractive correction to 6/24, L 6/60 improved by refractive correction to 6/24—

Her pupils were wide and reacted only slightly to light. There was questionable pallor of both optic discs. There were opacities in both lenses.

Examination showed a peripheral loss in the temporal half of each field, not symmetrical, a complete temporal green blindness, and an incomplete temporal blue blindness. Examination otherwise, including, x-ray negative.

Thyroid extract in $\frac{1}{2}$ grain doses, 4 times daily, was prescribed, but had to be discontinued on account of nausea, vertigo, anorexia and a rapid pulse, and pituitary extract was substituted.

When last seen (June 2, 1916) she felt that she was better. Though tests showed no improvement in vision, she thought she could see better. The absence of measurable improvement in vision may perhaps be accounted for by the presence of lens opacities.

Case 5

Case 5 (75-19)—Mrs. M. F., age 36, when first seen on October 9, 1907. Apparently quite well until six months previously. About this time her eyes were examined on account of long standing blepharitis. Glasses had always been satisfactory. Since then failure of vision of uncertain onset had occurred, very gradual in its rate of progress. When seen she complained of blurring, much worse in the left than in the right eye, and of headaches, of a type similar to what she had experienced since childhood.

Married at 23 years of age, she had had two children, no miscarriages. Menses had never

been very regular, usually six weeks intervening, and she had menstruated only once in the preceding six months. She was not pregnant. Hands, feet and face normal.

General health always good. Family history negative, grandparents living to old age.

Examination showed V. R. 6/36, not improved by glasses, L 6/60—, fingers in the nasal field. Pupils reacted slightly. R. O. D. was normal in appearance, but the inner $\frac{1}{2}$ and especially the lower inner quadrant of the L. was pale in comparison with the R.

Examination of fields showed the presence of a bitemporal color hemianopia, with some contraction of the peripheral fields for white. See charts. X-ray examination suggested some calcification or ossification of the capsule of the gland, but was not very definite.

On October 12, R. V. was 6/18+3, L. V. fingers in the nasal part of the field. She was given Iodide of Potassium and later Fowler's solution over a period of about six months without any material change in visual acuity, but with further limitation of the visual fields. Then thyroid extract in either one or two grain doses, twice daily was substituted for all other medication. Three months later her vision had improved to 6/6—2 in the R. eye, that of the left remaining unchanged. She felt better, was less thirsty and had no headache. There was no improvement in her fields. Her vision and generally improved condition were maintained over a period of 10 months after the commencement of thyroid feeding. She then passed from under my observation.

I learned later that she had been operated upon by Cushing, without benefit.

The dosage in the cases quoted and in the five here reported, has varied from 1 to 20 grains daily, and the results seem to have been the same. The material is insufficient to arrive at any reliable conclusion as to how much should be given, but as far as it goes it would seem to indicate that the quantity was of less importance than the nature of the drug itself.

In presenting these cases I do not wish to be understood as holding a brief for thyroid extract as opposed to pituitary extract. With one exception the cases did so well with thyroid that it was continued. I have had practically no experience with the use of pituitary extract.

These cases present symptoms of a mixed type, making it inadvisable to base on them any opinion as to the value of thyroid treatment in any particular form of pituitary disturbance.

thyroid from time to time, otherwise vision would begin to fail and headaches return

In view of cases like the last three it is difficult to refrain from entertaining the thought that in some cases showing pituitary symptoms, the primary factor is some thyroid insufficiency causing a compensatory pituitary hypertrophy

Case 1

Case 1 (9538)—Mrs W E G, age 67, first seen on September 29, 1921, when she gave the following history Since the end of 1920 her vision had been getting blurred, the left eye being the more affected of the two, although it had previously been the better eye She had had a great deal of pain about her eyes, beginning with the left, and in the occipital region Her vision had been variable There was no history of any enlargement of hands or feet

Polyuria was present but she did not admit polydipsia She had gained 10 lbs in 5 to 6 weeks During July, 1921, she was in bed on account of "nerves" When seen she was able to count fingers with her right eye at 3 feet, while with the left eye she was only able to distinguish hand movements in the nasal part of the field Pupils were rather large but reacted fairly well There were some striate opacities in her left lens, and possibly some pallor of both optic discs

Examination of her fields of vision on October 10, with a 10 mm white object showed an almost complete loss of the temporal half of each, the loss involving also the upper quadrant of the nasal field, the lower quadrant being damaged peripherally

In an x-ray examination of her skull neither the anterior or posterior clinoid processes were made out.

Thyroid extract grains 2, twice daily was prescribed at her first visit September 29 On October 10, she was able to count fingers with the right eye at 9 feet and the vision of the left eye had risen to 6/60+1 On October 31, the vision of her right eye had improved but little, while that of the left had risen to 6/12— Her fields also showed a marked increase in size The treatment was continued for 6 months with gradual improvement in her condition, so that when last seen April 4, 1922, vision of the R had improved to 6/60, and the left corrected to 6/6—3 or 4

The improvement in the fields is best appreciated by the charts herewith presented Briefly they underwent gradual but steady improvement so that by April, 1922, the left was completely restored except for about 20° at the temporal margin That of the right also improved markedly, though the last chart shows some loss as compared with the preceding one It is possible that the discrepancy may be an error of observation

due to the low visual acuity and perhaps less perfect fixation

The best information I can get indicates that the visual improvement was maintained until her death of Bright's disease about 18 months ago

Case 2

Case 2—Mrs M E C, age 64, was first seen on October 9, 1917 She complained of a shooting pain through her right eye, blurred vision, so much vertigo that she was afraid to get up to walk, and headaches coming on at night for the preceding two months

She had been gaining weight all the summer, going from 130 lbs to 150 lbs Both polydipsia and polyuria were present She was wearing a No 7 glove whereas she formerly wore a 6¼, a 5½ to 6 shoe whereas a year before she had worn a No 5

Upon examination her vision was 6/12 in each eye, the left being a little worse than the right, and was not improved by glasses Pupils normal Ophthalmoscopic examination was negative Some faint lenticular opacities seen after mydriasis

Examination of her fields showed a normal periphery, but a faint though definite color scotoma on the temporal side of each fixation point.

Thyroid extract grains 2, tid was prescribed. Under this medication her general condition improved remarkably When she was last seen Jan-24, 1918, she was free from pains in her head, and felt quite well The vision of each eye had risen to 6/6, and with both together she was able to read all the letters of the 6/5 line

She had had no return of these symptoms at the time of her fatal illness in the early part of 1923

Case 3

Case 3—Mrs H M, age 57, came for examination May 14, 1915 She gave a history of gradual failure of vision of the L eye for about 7 years, much worse during the past year, and of some recent failure of her right eye Of late there had been some aching in her eyes, and also some dull frontal headache, to which she had previously not been subject In the past two or three months she had been subject to drowsy spells about 2 p.m. She had always been in the habit of drinking a lot of water, but more since the menopause which occurred at about 42. There was some polyuria Night sweats for the past seven to eight months Her hands and feet have enlarged, and she wears a shoe a size larger than formerly

Examination showed V of R eye 6/18—, of the L 6/60 (coming and going) There was a bitemporal hemianopia, and the left optic disc

Mrs. D, aged thirty-four, husband and four children living and well, entered the Memorial Hospital February 16, 1918, with a diagnosis of gastric ulcer. Stomach symptoms began five years before, accompanied by much pain in the epigastrium and frequent vomiting. She vomited blood several times. She was told by a competent internist that she had a gastric ulcer and spent ten weeks in a hospital under dietary treatment. She was better for a time but had recurrences of heartburn, belching of gas, and frequent vomiting. Physical examination revealed a somewhat obese woman with excellent color, who looked unusually well. Aside from some tenderness in the epigastrium and right iliac regions, the physical examination was practically negative. While in the Memorial Hospital, x-ray examination of the gastro-intestinal tract showed a filling defect at the extreme pyloric end of the lesser curvature with marked irregularity of the duodenal cap. The stomach was empty at the end of six hours. A diagnosis of ulcer at the pyloric end of the lesser curvature or of the duodenum was made by the roentgenologist. Gastric analysis was normal and six stools were negative for occult blood. The tonsils were found to be large and infected and were removed two months after entrance to the hospital.

The patient improved somewhat under medical treatment for ulcer but after her return home continued to vomit at frequent intervals. The tenderness in the region of McBurney's point became quite marked and it was felt that chronic appendicitis might be reflexly causing her gastric symptoms. Appendectomy was performed on July 12th. The body of the stomach was found to be normal. No evidence of ulcer of the stomach or duodenum, nor of gall bladder disease was found. The appendix was very much bent upon itself and almost buried in adhesions. The pathological report was chronic and acute appendicitis.

We now congratulated ourselves that with the removal of a definitely diseased appendix, the cause of the trouble had finally been found, but while the patient was still in the hospital convalescing from her operation, vomiting and gastric symptoms again returned.

At this time considerable psychic unrest was noted. Further study along these lines brought out the following story. Her childhood was rather unfortunate in that her mother was a "bad" woman and the patient as a little girl knew of it. She married very young and soon found that she and her husband were not companionable. He was subject to outbursts of temper and was seldom kind or considerate. Since marriage he has continued to masturbate and his sexual habits have been such as to create disgust in his wife, so much so that she is cold to his approaches and finds them repulsive to her. Al-

though she can hardly endure intercourse with her husband, she is sexually active and probably suffers from the want of sexual satisfaction. Owing to the fact that there are four growing children she has felt unwilling to break up her home and leave her husband. Until such time as the children are able to care for themselves, she feels that she must carry on.

With this patient, we are undoubtedly dealing with a gastric neurosis, which passed under the guise of a gastric ulcer and was not at all relieved by the removal of a definitely diseased appendix. It is quite possible that the vomiting may be a physical expression of the disgust which her husband inspires in her. I have seen her from time to time since 1918, and although her condition is somewhat improved, she continues to vomit and to display nervous symptoms. While the social condition continues as it is, she probably cannot be cured.

A married woman in the early thirties had a nervous breakdown several years ago. Since then she has been blue and depressed and complained of palpitation and fatigue. It was difficult for her to take a cheerful attitude toward life, although her husband was kind and she had many things to make her happy. She spoke of her early childhood with much pleasure and felt that she had been carefree until the age of thirteen. At that time when called upon to stand and recite in school she became much confused and found considerable difficulty in getting through her lessons. It was at this age that she first learned that she was an illegitimate child. She was eight years old when her mother emigrated with her to America, and married here. The man whom she was taught to call father always treated her well and although three other children came, she really was his favorite. When she became old enough to understand the truth about her parentage, she became very sensitive, felt that she was being looked at and pointed at, and could no longer mingle freely with her playmates. While under treatment for her nervous condition she talked very frankly about her life and felt considerable relief from so doing. Although the cause of her disturbance cannot, of course, be removed, she may be able to so adjust herself to the situation that her life will be nearly normal.

A young woman twenty-three years of age had spent in bed three out of the previous four years and was regarded by all as a hopeless invalid. Her father was a pronounced alcoholic and had not lived with his family for many years. There were seven brothers and sister, many of whom showed neurotic traits. The patient graduated from High School at the age of nineteen years, when she began to complain of pain around the waist which was so severe that she was unable to

IS PSYCHOTHERAPY WORTH WHILE? REPORT OF ILLUSTRATIVE CASES

By JOSEPH R WISEMAN, A.B., M.D.

SYRACUSE, N. Y.

A MARRIED woman in the middle forties, the mother of several children, who had always enjoyed perfect health, became irritable and developed difficulty in sleeping. She had a fluttering sensation in the epigastrium and awakened in the morning with a number of loose stools. Her mental state became very much depressed and almost everything that happened seemed to produce worry. She worried over her husband, her house, the children, their plans for the future and other things without end.

Physical examination failed to reveal any cause for her symptoms and after several weeks of observation, I assured her that her troubles were psychic in origin and that there must be something that was disturbing her. She maintained that there was nothing on her mind, that she had talked to me freely and frankly, and had not concealed anything. One morning she sent for me, appeared greatly perturbed and said that she had something to confess which she had been unable to bring herself to talk about. She then told a story of unfaithfulness to her husband. Although apparently living a happy married life, she had had a lover for about ten years. She had always realized the sinfulness of her life, but it was only within recent time that psychic disturbances had developed. The patient is a refined woman, who lives in one of the higher planes of society and is thoroughly respected and beloved by all of her friends. She now seemed to feel keenly the false position in which she found herself and maintained her sincere desire to end all wrongdoing and to live only for her husband and family. One might have thought that having reached this point in the analysis of her mental state and having revealed the chief focus of psychic disturbance, the rest of the cure should have been easy. The reverse was just the case.

The patient plunged into deeper depression, sleep became even more difficult, she could not bring herself to smile and threatened suicide. The cause of these symptoms was the terrific mental conflict which had now been precipitated. On the one hand the results of all her moral and religious training showed her duty only too plainly, and to this her finer nature responded. On the other hand, her lover exercised an intense attraction which she was striving with the greatest difficulty to overcome. While the conflict was at its height her mental state was most distressing, but with the passage of weeks her better nature began to assert itself. Her state of mind became calmer, depression slowly gave way to cheerfulness, and finally after the lapse of a number of

months, she seems to be entirely cured. She is now living a normal life and never refers to her former state.

An unmarried woman now in the late thirties has been under observation for eight years. Her life has been a rather unhappy one. As a child she was precocious, hypersensitive and a very poor sleeper. The slightest noise would awaken her. Her mother died when she was twenty-one. During the last few years of her mother's life, there were a number of conflicts between them, in which the patient thought that her mother had treated her quite unjustly. In spite of this, she loved her mother devoutly and after her mother's death, her grief was very intense. For years she could not bear to talk of her mother and it distressed her greatly to visit her grave. She had had a number of love affairs, none of which ended very fortunately for her. She kept company with one young man for several years and was engaged to be married, but he was evidently beneath her station in life, as well as her inferior in character and intelligence, and the engagement was finally broken. After her mother's death she had charge of two younger brothers, whom she brought up and mothered. Her father died about seven years ago. Two years ago a middle-aged man with wife and four children began to pay her attention. She was obliged to meet him frequently in a business way and at first was not in the least interested in his attentions to her. He was, however, very persistent and after a time she began to care a little for him. As the months went on, a love affair developed.

The patient is a woman of refinement and splendid character and has always lived a life beyond reproach, yet she seems unable to resist the attraction of this man, who seems to care so much for her. There has been nothing between them more than a considerable amount of love making, yet both understand the dangerous possibilities. The patient realizes that if the affair became public, she would lose the high esteem in which she has been held and has threatened suicide if this should occur. In spite of this and in spite of her religious training as a devout Catholic, she seems absolutely unable to resist. She has been subjected to a rather exhaustive psycho-analysis and the situation has been thoroughly argued out, yet the affair remained for months in statu quo. Only recently has she shown signs of breaking away from his influence. She sees him less often but it is difficult to predict what the outcome will be.

GOVERNOR SMITH'S

The annual message of Governor Alfred E. Smith, which appeared in the morning papers on January 7th, is of great interest to physicians. Governor Smith has always stood for scientific medicine and in his message he emphasizes medicine and public health equally with other civic topics, such as taxation, highways, and county affairs.

It is something almost unique for a Governor to take a deep interest in health, and still more so to demonstrate abroad understanding of the sub-

ANNUAL MESSAGE

ject and a grasp of the point of view of the medical men, on whom fall the ultimate responsibility for public health.

It is the desire of all right-thinking men to free our State from quackery and medical fraud. In this great work Governor Smith stands for the best ideals of the medical profession. The extracts from his message, which we are printing on page 76 are of the nature of lay editorials which also reflect the consensus of medical opinion on legislative medical topics.

stand She had headaches, palpitation, weakness and pain along the spine She slept about four hours a night and had not exceeded this for years

The physical examination did not reveal sufficient cause for the various findings and the psychic study brought out the following history

Since childhood she has always had something to worry about She has been intensely religious, went to confession often and felt that she was a great sinner As a child of six, whenever she put on a new dress, she would at once proceed to tear a hole in it Her parents could not understand why she did it and the child steadfastly refused to explain The real reason was that she felt her sins to be so great that she must do penance, she enjoyed the new dress and therefore punished herself by tearing a hole in it She had an insistent idea that if she did not punish herself her mother and grandmother would die This obsession and the underlying thought of doing penance have caused her to perform numerous peculiar actions all her life At no time during the day or when awake at night is her mind free She has no right to enjoy herself or to feel happy Whatever she would like to do she denies herself so that she may do penance She is unable to put down the simplest object for fear that it will be put in the wrong place, and will sometimes spend an hour before she can induce herself to part with it She is afraid of the dark, afraid of various animals, afraid of contagious diseases, and has all kinds of fearful terrifying dreams

It was found that the patient was very suggestible and amenable to treatment along psychotherapeutic lines By a gradual process of explanation, suggestion and re-education remarkable results were obtained Life began to take on a new aspect and the patient commenced to feel that she had a right to be happy Even the character of her dreams changed, and instead of terrifying visions which caused her to jump out of bed with fright, her dream life became pleasant with scenes of fields and flowers predominating An entirely new being seemed to be created and she can now look back upon her former self as almost another personality From a wretched unhappy invalid in bed most of the time, unable to help herself, sleepless, racked by pain and tortured by all manner of abnormal mental processes, she has been transformed into a young woman who is care-free and happy She

has now been holding a clerical position for several years and is able to work steadily, seldom losing a day because of illness

Patients like those I have discussed are not isolated examples which we rarely see They are exceedingly common in the practice of every physician, whatever may be the specialty he has chosen to follow The careful surgeon has come to learn that a certain type of patient who is perhaps only too willing to have an operation, needs psychic study rather than operative skill. The gynecologist too probably sees many of this group, but to the general practitioner and to the internist they come in largest numbers Are we as a profession alive to our opportunities and our responsibilities in treating those who perhaps have bodily symptoms but really are mentally sick?

To do justice to these patients three essentials are needful time, patience and some knowledge of psychological mechanisms If the physician will take the time to tactfully win the confidence of the patient and gradually bring him to tell a full story of his trials, worries, hopes and ambitions, a large step toward the cure of that patient will already have been taken The mere recital to a sympathetic listener of the conflicts that have harried the soul, perhaps the confession of things that have never before passed the lips, give a tremendous sense of relief Some physicians who perhaps have never paid much attention to formal psychology are, nevertheless, such shrewd observers and keen analysts that they are remarkably successful in quickly bringing to the surface the conflicts in the depths of the patient's mind Many of the simpler cases will respond beautifully to common sense explanation and advice For the more deep-seated and more complex neuroses, the services of one who has paid special attention to mental analysis will assuredly be needed, for the task is long and difficult After psychic study, whether long or short, gives us adequate cause for the patient's symptoms, we are then in a position to explain to him just how his neurosis came about in a manner that will carry conviction Following this we have to build up his morale, teach him how to avoid the faulty mental habits which such individuals always show, and to adjust his life to a new mental viewpoint The results will usually repay the time and effort expended

that sociological relief belongs to other groups. One of the greatest burdens of country practice, a generation ago was the necessity that a doctor should furnish relief, not only professional but also sociological. The reason was that when he went to a home, he often found nothing to work with. A health officer, for example, was called at night to see a young woman who had just returned from the city with a bad sore throat which was recognized as obstructive diphtheria. He summoned two doctor friends, and while one assisted in doing a tracheotomy, the other drove his automobile ten miles through a thick fog in order to get the mother to come and care for the patient,—and he had the longest and hardest duty of the three.

Physicians believe that public health nursing societies, tuberculosis committees, and other organizations interested in public health have an essential place in making medical service available to everybody in a community. Their field is not that of the practice of medicine, for that belongs to the doctors. Their field is to provide the auxiliary aids by which doctors may work to the best advantage without assuming sociological burdens.

Civic consciousness in public health matters is of recent origin, and the boundaries between the fields of action of physicians and those of lay organizations have been loosely defined. However, the time has come when those limits can be defined so clearly that serious disputes may be avoided.

The sociological phases of public health are

practiced almost exclusively by organizations, from departments of health down to charitable societies. These have always been largely impersonal, without emotion or feeling. But when they come in contact with individual doctors, they deal with personalities who have deep emotions and are ready to express their feelings,—which are not always pleasant.

One solution of the difficulty lies in organizations of physicians. The machinery is at hand ready to use,—the medical societies of the counties, the State, and the Nation. Physicians recognize their civic duties, and are performing them largely by means of their medical societies. The physicians will retain their individualism and independence unimpaired, but in their relations to lay public health organizations, they will speak by means of their own medical societies. If it is a material issue, the American Medical Association will represent the doctors, if the issue is State-wide, the State Medical Society will act, if it affects a county, the county medical society will act, and if the issue is local, a committee of the county medical society will represent the doctors.

The question of medical paternalism will be solved by the joint action of medical societies and lay organizations. Medical societies are receptive to invitations to cooperate with lay societies in organizing clinics, hospitals, educational campaigns, and all other phases of public health work. If the invitations are extended to the medical societies, their members will provide medical services and the medical information and advice that are needed to carry on the contemplated public health work.

NEGLECTED FIELDS OF PRACTICE

Russell Conwell made a fortune for Temple University by his lecture on "Acres of Diamonds," the burden of which was that around every one of us there lie unnoticed opportunities for acquiring fame and fortune along lines which are useful to our fellows. Hosts of patients whom physicians could help if they would are seeking quack relief because their doctors do not want to bother with them.

Geriatrics is a specialty of increasing importance whose very meaning is strange to many doctors. More people than ever are reaching old age, and larger numbers have the means for paying a doctor for relief from their aches and worries. Children are anxious to do their full duty to their aged parents, and to give comfort to the old folks. A doctor who can please an aged parent and give a querulous octogenarian relief and sleep is a benefactor. Yet how many physicians besides few old family doctors have given serious thought to the diseases of old age?

At the opposite end of the span of life are the children. Pediatrics is a field that is scarcely

touched by the general practitioner. A recent study of a series of mothers of young children (*Long Island Medical Journal*, July, 1925), showed that only now and then did one consult her family doctor, for advice regarding feeding, sleep, recreation, and other conditions affecting her offspring, unless the child was actually sick. Also it was found that few doctors cared to have mothers bring their well children to their offices, and many doctors had even told mothers to go away and forget the children's troubles for they would soon be outgrown. Preventive pediatrics is a neglected field which doctors could cultivate with great benefit to themselves as well as to their patients.

Physiotherapy is a branch of medicine that belongs to physicians and they are beginning to realize their duties to relieve backaches and leg pains, and all the uncomfortable states that quacks promise to ease. It requires money to purchase the necessary apparatus, and time to apply treatments. But patients are satisfied when they leave the office with limber joints.

PATERNALISM IN MEDICINE

Much is said against governmental paternalism. The American spirit upholds the development of originality and initiative by individuals, be they persons, towns, counties, states, or nations. When each individual person or governmental unit develops an independence of action, and fills its own wants, strength of character and efficiency of accomplishment are ensured. There are some problems so big that only the nation can solve them. Other problems are peculiar to the individual person. The nation makes itself almost ridiculous when it attempts to do what a citizen is expected to do for himself.

The American people exhibit two contradictory characteristics,—on the one hand, individualism and personal independence, and on the other, paternalism, or the acceptance of assistance from those more powerful and resourceful than themselves. A great factor in the growth of paternalism is the selfish desire of the individual to get something for nothing.

In their intense desire to give every citizen an equal opportunity to secure and maintain an equal share of life, liberty, and the pursuit of happiness, they petition their higher governmental bodies to provide the means by which those in the next lower class may secure all the advantages enjoyed by those in the most favored group. Then when the assistance is voted, those in the lower groups demand a share of the assistance regardless of their own need of help. If one state gets needed assistance from the national government, then all the other states demand the same dole regardless of their own resources.

While the theory of governmental help to the needy is commendable, yet in practice it bears the undesirable fruits of "paternalism," "special privileges," and "pauperism." These and other strong terms are used by writers and speakers in calling attention to perversions of the intentions of lawmakers and governmental administrators.

Dr Dwyer, Professor of Economics at the Vanderbilt University, speaking at the dinner of the Southern Society in New York City recently, bemoaned the paternalism of the Federal Government in its interference with the internal affairs of the States. Judge Guy L. Fake, former judge of the Rutherford (N. J.) District Court, writing in the "New York University Alumnus," expresses pointed thoughts regarding some unwise governmental inroads into medical fields when he says:

"Among the inspiring beneficences which we now seem to enjoy at public expense, and which had no place in reason or prophecy a decade ago, might be mentioned our public nurses, who go about doing good, treating and advising folk as though the folk were in forma pauperis, none of which folk actually are paupers, however, but merely laboring under a government induced de-

lusion of helplessness, and foolishly believing they are getting something in the way of service for nothing. In one case, the wife of a very wealthy man received personal instruction on the care and nursing of her baby, for which she paid only in a pro tanto loss of self respect, no coin of the realm being taken from her by the government nurse for such invaluable services as were rendered. These nurses, by the way, were foisted upon our community a long way from home, through an Act of Congress at Washington, under which the State legislature felt the necessity of choosing federal aid bribe money, rather than suffer the anguish which would be produced by the thought that our federal tax money would be spent by some other bribe-accepting state if we did not divert some of it to our own coffers, and so here we are in a town where we have heretofore had one of the lowest death rates in the whole glorious union, where we have today no poor problem, no foreign population and no factories or factory problems, accepting public nurses into our beautiful well appointed private homes as though we were beggars at the public crib, and all our uplifters joyously join in a halleluiah chorus of praise and thanksgiving for this so-called free service."

When thoughtful laymen give expression to these views, physicians may properly state the basic principles on which to mold their attitudes toward governmental medical agencies.

The present system of distribution of medical service to the people is a natural evolution, and is founded on the desire of both the people and the doctors. It is essentially individualistic in distinction from communal and paternal. Each individual seeks to choose one doctor to whom he may confide his pains and disabilities. Even a big city hospital assigns a case to a particular doctor, and the patient goes away talking about "my" hospital doctor. Individualism in medicine is here to stay, and all attempts to substitute state medicine in any form are contrary to historical precedent and modern custom.

But what about those persons who are unable to employ a doctor or provide the means for carrying out the doctor's advice? It is for these people that sociologists have proposed state medicine, health centers, public health nurses, child welfare clinics, and other paternal means of giving medical treatment to the needy. This relief consists of two elements:

- 1 Professional advice and treatment

- 2 Sociological assistance in the form of money, nursing, hospitalization, education, and other means whereby the patients may be enabled to follow the medical advice.

Physicians have always been willing to contribute their professional services to the needy without hope of fee or reward, but they believe

treatment or cure, may be disciplined by this committee

This committee likewise has power to adjust controversies between physicians and to arbitrate controversies between physicians and third parties should the parties to such controversy agree to such arbitration. It is felt that many cases against physicians for alleged malpractice that now are brought in the courts may ultimately be disposed of promptly, fairly and economically through the use of this power of arbitration, and as this committee gains the confidence of the profession and the public, we hope to find a very material reduction in the number of suits brought against physicians.

Thus, the first step in procuring legal security to the profession through self government will have been accomplished, and the succeeding steps in the proper legislative program to restrain unlicensed practitioners can be taken with confidence of public support and successful result.

Heretofore the prosecution of unlicensed practitioners has been at the instance of the medical profession and under the present law the profession is entitled to receive the fines and penalties that are imposed for violations of the act. This practice has made it appear that the contest in court in the prosecution of the unlicensed practitioners was one between the profession on the one side and the individual violator on the other. Whereas the underlying theory of criminal prosecution is that it must be in the interests of the public and that the party plaintiff must be the people of the State of New York. Heretofore evidence for such prosecutions has been gathered by the county societies through investigators employed by them. This has placed an expensive burden upon such societies in the performance of general police duty. The statement of this condition under the present law is sufficient to condemn it. The bill, which has earned the support of the Society contemplates a different procedure.

The Board of Regents, acting through the Board of Medical Examiners, are authorized to employ not less than five or more than seven inspectors, whose duty will be the investigation of cases of unlawful practitioners. The Attorney-General of the state will prosecute the offenders, except in counties having a population of half a million or more, where the district attorney will act. The delay incident to the present procedure of prosecution by indictment of a grand jury is obviated by conferring jurisdiction upon the courts of special sessions which may act without a grand jury indictment and upon an information of the Attorney-General or district attorney and where summary trial and conviction can be had without delay.

The title of "doctor," which is now greatly abused by chiropractors, chiropodists and others upon whom it has not been lawfully conferred, when used "in the conduct of any occupation or

profession involving or pertaining to the public health or treatment or cure of any human disease, pain, deformity or physical condition" is made a misdemeanor, unless the person is authorized by law to use the title. The enforcement of this one provision would remove from thousands of signs that deceptive title. The rules of evidence against offenders are greatly simplified by making certain acts presumptive evidence, as the use of a person's name on a sign is presumptive evidence that the person whose name is so used is responsible for the use without having to prove who painted the sign and who gave the order for the same. In this way there can be removed many of the alluring advertisements of the unlicensed practitioners, for it is through these that their trade is carried on.

As the law presumes that every licensed doctor possesses reasonable skill and in the treatment of a case has done his duty, the converse should be presumed in the case of an unlicensed practitioner. So that a provision is made in the bill whereby a person who has been injured as a result of a treatment given by an unlicensed practitioner does not affirmatively have to prove negligence, but may rely upon proof of the fact that he suffered such injury and that the person inflicting it in the course of a treatment, was not a licensed practitioner. The creation of this rule would lay a heavy burden of legal responsibility upon those who practice without a license and would make the proof of their liability simple and inexpensive.

In order that under this new bill we should have a fresh start with a clear list of names of those who are lawfully licensed to practice, the bill requires one registration on the part of those now practicing, the names of those that are hereafter admitted to practice will be added as they register and the names of those whose practice is terminated by death will be reported to the Regents through the Board of Health. The Department of Education expresses doubt as to the adequacy of this system of registration and favors an annual registration. Only experience under the act will enable us to tell ultimately whether their fears are justified. The registration, however, will be the first complete roll call of the profession since 1880 and is imperatively necessary. The profession should have an open mind on whether or not, in the light of experience as it is gathered in the future under this bill, further registration may be necessary.

Harmonious co-operation between the profession, the Regents, the Department of Health, the Attorney-General's office and the courts will be imperatively needed to make the operation of this bill, if enacted into law, satisfactory. The bill has received the support of these different agencies in its present form and with adequate effort to procure its passage should become a law this year.

and happy faces, and they come back in a day or two for more treatment. Those doctors who practice physiotherapy seriously have full waiting-rooms. Doctors in general practice should make use of physiotherapy for the sake of the honor of their profession, if for no other reason.

Especially should hospitals provide the equipment for giving treatments in physiotherapy; and medical schools should give instruction in the various methods which any general practitioner can apply.

Psychiatry is a vast field that doctors neglect. The world is full of neurasthenics who seek in

vain for mental therapy from general practitioners, and many find satisfaction in the mental suggestions of Christian Science readers. The State Hospitals have many cases whose insanity could have been prevented by the methods of applied psychology which general practitioners could readily learn to apply.

The people look to their family doctors to advise them in all medical matters. The methods of relief and prevention are available to all doctors. It is the duty of physicians to cover the neglected fields of practice in which they could readily become proficient.

"PTOMAINES" POISONING

The State Department of Health frequently receives death certificates in which the cause of death is given as "ptomaine" poisoning. While this might have been accepted as a satisfactory cause of death a generation ago, it is no longer either scientific or acceptable. Investigation of deaths reported as due to ptomaine poisoning show that the cases have usually died after showing severe gastro-intestinal symptoms from causes which the physicians have not determined accurately. It is an old observation that "spoiled" food, especially if it had been canned, sometimes causes severe vomiting and diarrhoea, and in these days a history of the patient having eaten old canned food may usually be obtained and may be utilized as a convenient excuse for a meaningless diagnosis.

When bacteriology was a young science, attempts were made to identify the poisonous substances in spoiled food with apparent success, and the theory of ptomaines and leucomaines was developed. Gould's Medical Dictionary, 1891 edition, defines ptomaines as "putrefactive alkaloids," and says that the word is derived from the Greek word "ptoma," a corpse. It defines leucomaines as "basic substances found in living tissues either as the products of fermentative changes or of retrograde metamorphosis." It derives the word from the Greek "leucoma,"—white of egg. The principal difference between the two classes of substances was that ptomaines were formed in dead bodies and leucomaines in the living. Ptomaines were supposed to be the more poisonous of the two substances, but the importance ascribed to leucomaines is shown by the following quotation from the 1891 Edition of Gould's Dictionary:

"The aqueous extract from vapors exhaled by dogs has been found to cause death within 24 hours when injected into the veins of other animals. The same violent poison is said to

produce pulmonary phthisis in confined air by continuous influence."

The idea of a fundamental difference in the poisonous qualities of living and dead tissues is also shown by the division of pathogenic bacteria into two classes, those growing outside of the body, and those growing in the living flesh. Gould defines *sapraemia* as "A febrile condition due to introduction into the blood of the chemical products of putrefaction," and *septicaemia* as "an infective disease caused by the absorption of septic products." A physician who studied medicine during the decade of the nineties absorbed these conceptions and adopted them as a part of the permanent equipment of his brain from which they could be displaced only by considerable study.

The decade and a half following 1891 witnessed a great clarification and amplification of the former knowledge of infective processes. Accurate methods of culturing micro-organisms were discovered and the practical theory of susceptibility and immunity was formulated, the specific nature of fatal gastro-intestinal infections was demonstrated, the nature of botulism was shown in great detail, the relation of para-typhoid diseases in cattle and mice to gastro-intestinal forms of human diseases was shown, and the relation of human carriers to many acute gastro-intestinal disturbances was proven. It was also demonstrated that the common process of putrefaction had little to do with human disease, and the very word *ptomaine* fell into almost complete disuse in scientific circles, just as the word *typhilitis* became almost forgotten when the term *appendicitis* took its place.

The older health officers who have taken courses of instruction under the New York State Department of Health know the long hours and close thought spent in acquiring the bacteriological conceptions that have been de-

geographical pathology the latter is believed to be almost immune to this manifestation of syphilis, although the disease *per se* is known to be fearfully common and in some regions is endemic and familial. Severe cutaneous late lesions prevail extensively, which *a priori* would argue against the presence of neurotropic manifestations. But, as the author states, with a percentage asylum population of 75 for males and 25 for females, there must be much more metasypilis in Turkey than has been heretofore believed. He makes no statement concerning the incidence of tabes which might throw some light on this question. Of interest is the statement that the universal prevalence of malaria in Turkey may tend to prevent the development of paresis.

Sympathectomy in Angina Pectoris—The favorable results following resection of the cervicothoracic sympathetic for the relief of angina pectoris (see this JOURNAL, November 15, p. 1031) are still being recorded in various periodicals. In the *Archiv für klinische Chirurgie*, September 19, 1925 (cxxxvii, 1), Hesse reports four cases with three complete recoveries, i. e., permanent cessation of the painful crises. One of the three patients thus benefited died later and at autopsy extreme lesions of the heart and coronaries were found, yet he had passed the balance of his life quite free from pain. Adding his 4 to 58 cases culled from the literature, he sums up the results in the 62 cases as follows: died as a result of operation or of the basic disease, 18; survivors, 44, all but three of whom were improved and 31 permanently relieved of pain by the intervention. In theory the left side is superior for sympathectomy save when there is a preponderance of right-sided symptoms. Many objections have been made to the theory of the operation, which may mostly be reduced to the deficiency symptoms due to nerve division, but the operation is of too recent a date to permit of conclusions as to remote results. It seems beyond doubt, however, that division of the depressor nerve is open to too many and valid objections and should not be attempted. The author gives no less than five cogent reasons for not attempting this division. In conclusion Hesse states that angina pectoris still remains in the long run a medical disease with surgery a reserve hope for cases which have resisted all kinds of treatment by the internist.

G. Hofer, in discussing the pros and cons of the operation in the *Wiener medizinische Wochenschrift* for October 31, 1925, expresses the belief that we are still in need of much more extensive experience before we can decide with certainty when to operate, and before we can be sure that the operation has succeeded in curing the patient. He agrees with Hesse that we should not think of surgery until every medical

resource has been tested. With proper selection the danger of an operative fatality will be at a minimum, but the prognosis as to recovery will probably remain uncertain.

In an article entitled "The Neurological Mechanism of Angina Pectoris and Its Relation to Surgical Therapy," Wilder Penfield (*American Journal of the Medical Sciences*, December, 1925, clxx, 6) remarks upon the surprising vagueness as to the rational indications for the various surgical operations employed for the relief of angina pectoris, and upon the fact that the ablation of different nerves and ganglia has been carried out blindly, in some cases, with no apparent working hypothesis as to the relation of those nerves to the heart. He describes two cases in which, following operation, angina was felt in the area where the sympathetic motor supply was intact. In the first case, one in which severe angina began in the manubrium and extended to the inner aspect of the left arm and then to the inner aspect of the right arm, the middle and inferior cervical and stellate ganglia were removed, leaving in place both superior cervical ganglia. It was impossible to explain the continued attacks on the basis of referred pain. The angina which the patient experienced was in the distribution of the fibers of the superior sympathetic ganglion which accompany the branches of the fifth nerve and upper three cervical nerves, but this ganglion is cut off from the central nervous system. The author therefore assumes that the ganglion is stimulated by a reflex in the autonomic system. On the theory of an axone reflex, the conditions are exactly the same as those in which reflexes occur elsewhere in the sympathetic nervous system. By stimulation of the sympathetic axones in the cardiac plexus, the motor cells in the intact sympathetic ganglia would be excited, causing localized sweating, arterial spasm and some increase in blood pressure, phenomena which were manifested in these cases. This new hypothesis for the explanation of the nervous mechanism of angina pectoris is based upon an autonomic reflex. It might well be called, therefore, "reflex pain." It causes peripheral spasm of smooth muscle and may thus resemble the pain in various angiospastic conditions. It differs from the referred pain of Head principally in that the point of contact of sympathetic and cerebrospinal systems is shifted from the posterior root to the periphery where there are other analogous contacts between the two systems. The practical conclusions to be drawn are that the removal of a sympathetic ganglion removes the possibility of angina pectoris in the motor distribution of that ganglion only. Pain is still possible in the motor distribution of the remaining ganglia, provided the stimulus arising in the heart or aorta is adequate. Success in the

MEDICAL PROGRESS

The Humanity of Chemical Warfare—The condemnation of the use of chemicals in warfare which was voted at a recent conference held in Geneva, on the theory that this method of warfare is inhumane and should be abolished, has led Lieutenant-Colonel H. L. Gilchrist (*The Military Surgeon*, November, 1925, lvii, 5) to call attention to certain facts showing the error of this attitude. During the past war there were 72,552 casualties from gas in our army. Of this number 200 died on the field of battle and 1,221 died in hospitals from the effects of gas exposure, giving a mortality of 2 per cent. There were 187,586 casualties from weapons other than gas. Of this number 46,519 or 24 per cent died, or twelve times as many deaths from those weapons as from gas. There were 754 men blinded in one or both eyes by war weapons during the war. Of this number gas was responsible for 29 or 3.8 per cent, other weapons being responsible for 725 or 96.2 per cent. War weapons other than gas were responsible for 9,147 permanently crippled soldiers. Gas was responsible for no permanently crippled. There were one and a half times as many cases of tuberculosis per thousand occurring among soldiers who were not gassed in France as there were among those gassed, which might be taken as indicating that gas acted as a preventive against tuberculosis. As a result of correspondence with over 3,000 physicians in this country and Europe familiar with gases, and with chemical manufacturers who have long produced gases similar to those used in war, from a careful study of the records of the Veterans' Bureau and veteran hospitals, and from continued laboratory research conducted at the Medical Research Division, Edgewood Arsenal, Colonel Gilchrist is convinced that in the great majority of instances persons suffering from exposure to lethal concentrations of gases show no permanent resulting pathological lesions. In a minority of cases some permanent damage is done to the lungs, but it is not widespread and is generally confined to small areas with the formation of fibrous tissue which is so small in amount as hardly to affect the functional efficiency of the organs. The author concludes that an exhaustive study of this subject shows conclusively that the use of chemicals in warfare is more humane than that of any of the recognized weapons.

The Comparative Rarity of Tabes and Paresis Among Primitive Folk—Professor Salomon, of Buenos Aires, writing in the *Deutsche medizinische Wochenschrift* of November 13,

1925, discusses the causes for the greater relative frequency of metasyphilis among civilized peoples than among the inferior races. One apparent reason is that the bone and skin lesions are more severe among the latter, and it is a matter of common observation that persons in whom the osseous lesions and skin eruptions are very pronounced are relatively protected against the metasyphilitic manifestations. This immunity is, however, not absolute and we do sometimes see neurosyphilis in cases in which the bone and skin involvement has been marked. One must therefore theorize cautiously. The hypothesis that the two forms of syphilis are due to different strains of spirochetes is not fanciful if we only admit that there was originally but a single species which has undergone a certain variation. This polyvalence of pathogenic organisms is no new thing, for it is seen in all infectious diseases and was long ago explained in a descriptive sense by some such term as "genus epidemicus." We see the same dualism in the bubonic and pneumonic forms of plague which are due to one and the same organism. Of possible contributory factors the author thinks we may eliminate alcohol and tobacco. Insufficient treatment of the secondary and tertiary stages with consequent severity of manifestation is a valid explanation so far as it goes. Men who have suffered from a febrile attack of any sort during the first year of syphilis seem immune to metasyphilis, a document in favor of the malarial treatment of threatened or actual paresis. Patients fortunate enough to make an early spontaneous recovery from syphilis or to recover perfectly with the aid of treatment so that no trace of the disease remains need not fear metasyphilis. A plausible hypothesis is that of weakened allergic reaction to explain the apparent immunity of the skin in syphilitics who develop metasyphilis. Allergic immunity is superficial and cannot involve the nerve centers which are then invaded by the spirochete. The author can find no basis for the belief that vaccination for smallpox has made a change in the clinical type of syphilis, for he has seen victims of smallpox develop metasyphilis.

Schürky, writing in the *Munchener medizinische Wochenschrift*, of November 20, 1925, on the postmortem diagnosis of paresis, states that in an autopsy material of 147 in an insane asylum in Constantinople, he found 37 cases, 25 per cent, of paresis. The 37 cases of paresis came from all parts of Turkey and thus raises the question as to the frequency of paresis in that country. In

geographical pathology the latter is believed to be almost immune to this manifestation of syphilis, although the disease *per se* is known to be fearfully common and in some regions is endemic and familial. Severe cutaneous late lesions prevail extensively, which *a priori* would argue against the presence of neurotropic manifestations. But, as the author states, with a percentage asvulum population of 75 for males and 25 for females, there must be much more metasyphilis in Turkey than has been heretofore believed. He makes no statement concerning the incidence of tabes which might throw some light on this question. Of interest is the statement that the universal prevalence of malaria in Turkey may tend to prevent the development of paresis.

Sympathectomy in Angina Pectoris—The favorable results following resection of the cervicothoracic sympathetic for the relief of angina pectoris (see this JOURNAL, November 15, p 1031) are still being recorded in various periodicals. In the *Archiv für klinische Chirurgie*, September 19, 1925 (cxxxvii, 1), Hesse reports four cases with three complete recoveries, 1 *e*, permanent cessation of the painful crises. One of the three patients thus benefited died later and at autopsy extreme lesions of the heart and coronaries were found, yet he had passed the balance of his life quite free from pain. Adding his 4 to 58 cases culled from the literature, he sums up the results in the 62 cases as follows: died as a result of operation or of the basic disease, 18; survivors, 44, all but three of whom were improved and 31 permanently relieved of pain by the intervention. Sympathectomy in Angina Pectoris—The favorable results following resection of the cervicothoracic sympathetic for the relief of angina pectoris (see this JOURNAL, November 15, p. 1031) are still being recorded in various periodicals. In the *Archiv für klinische Chirurgie*, September 19, 1925 (CLXXXVII, 1), Hesse reports four cases with three complete recoveries, *i. e.*, permanent cessation of the painful crises. One of the three patients thus benefited died later and at autopsy extreme lesions of the heart and coronaries were found, yet he had passed the balance of his life quite free from pain. Adding his 4 to 58 cases culled from the literature, he sums up the results in the 62 cases as follows: died as a result of operation or of the basic disease, 18; survivors, 44, all but three of whom were improved and 31 permanently relieved of pain by the intervention. In theory the left side is superior for sympathectomy save when there is a preponderance of right sided symptoms. Many objections have been made to the theory of the operation, which may mostly be reduced to the deficiency symptoms due to nerve division, but the operation is of too recent a date to permit of conclusions as to remote results. It seems beyond doubt, however, that division of the depressor nerve is open to too many and valid objections and should not be attempted. The author gives no less than five cogent reasons for not attempting this division. In conclusion Hesse states that angina pectoris still remains in the long run a medical disease with surgery a reserve hope for cases which have resisted all kinds of treatment by the internist.

G. Hofer, in discussing the pros and cons of the operation in the *Wiener medizinische Wochenschrift* for October 31, 1925, expresses the belief that we are still in need of much more extensive experience before we can decide with certainty when to operate, and before we can be sure that the operation has succeeded in curing the patient. He agrees with Hesse that we should not think of surgery until every medical

resource has been tested. With proper selection the danger of an operative fatality will be at a minimum, but the prognosis as to recovery will probably remain uncertain.

In an article entitled "The Neurological Mechanism of Angina Pectoris and Its Relation to Surgical Therapy," Wilder Penfield (*American Journal of the Medical Sciences*, December, 1925, CLXX, 6) remarks upon the surprising vagueness as to the rational indications for the various surgical operations employed for the relief of angina pectoris, and upon the fact that the ablation of different nerves and ganglia has been carried out blindly, in some cases, with no apparent working hypothesis as to the relation of those nerves to the heart. He describes two cases in which, following operation, angina was felt in the area where the sympathetic motor supply was intact. In the first case, one in which severe angina began in the manubrium and extended to the inner aspect of the left arm and then to the inner aspect of the right arm, the middle and inferior cervical and stellate ganglia were removed, leaving in place both superior cervical ganglia. It was impossible to explain the continued attacks on the basis of referred pain. The angina which the patient experienced was in the distribution of the fibers of the superior sympathetic ganglion which accompany the branches of the fifth nerve and upper three cervical nerves, but this ganglion is cut off from the central nervous system. The author therefore assumes that the ganglion is stimulated by a reflex in the autonomic system. On the theory of an axone reflex, the conditions are exactly the same as those in which reflexes occur elsewhere in the sympathetic nervous system. By stimulation of the sympathetic axones in the cardiac plexus, the motor cells in the intact sympathetic ganglia would be excited, causing localized sweating, arterial spasm and some increase in blood pressure, phenomena which were manifested in these cases. This new hypothesis for the explanation of the nervous mechanism of angina pectoris is based upon an autonomic reflex. It might well be called, therefore, "reflex pain." It causes peripheral spasm of smooth muscle and may thus resemble the pain in various angiospastic conditions. It differs from the referred pain of Head principally in that the point of contact of sympathetic and cerebrospinal systems is shifted from the posterior root to the periphery where there are other analogous contacts between the two systems. The practical conclusions to be drawn are that the removal of a sympathetic ganglion removes the possibility of angina pectoris in the motor distribution of that ganglion only. Pain is still possible in the motor distribution of the remaining ganglia, provided the stimulus arising in the heart or aorta is adequate. Success in the

operation depends not upon interrupting a direct afferent path from cardiac plexus to central nervous system, as has been assumed, but upon the interruption of autonomic reflexes. Complete cervico-upper-thoracic sympathectomy abolishes the pain, but should be employed only in cases in which life is really insupportable even under the best medical care. Removal of the superior cervical sympathetic ganglion does not render angina in the motor distribution of the other ganglia impossible. Its removal can be justified only on the basis of some resultant alteration in the coronary vessels or aorta which are innervated by it through the superior cardiac nerve.

Etiology of High Blood Pressure—In an article on this subject in the *Deutsche medizinische Wochenschrift* of December 11, 1925, Fleischmann discusses essential hypertension, secondary hypertension and arteriosclerosis from the various etiological angles. In speaking of the influence of race and diet, he mentions the Kirghis who live on mutton and kumyss, consuming daily enormous quantity of both (kumyss also contains 3 to 6 per cent of alcohol). They suffer considerably from the disease group comprising gout, obesity, and hypertension. The unsatisfactory state of our present knowledge of high blood pressure may be due to the fact that we do not direct our study on the comparatively young. Men over 40 have probably suffered for a long time, so that with age it becomes increasingly difficult to appraise the various causal elements. It is possible to isolate two of these, first the general group of gout, diabetes, obesity, and hypertension, and second the psychic factor. Those neurotic subjects with great vasolability constantly undergo increase of tension from the sum of the emotional factors, as grief, worry, excitement, chagrin, and anxiety over money matters, and the incidence of hypertension in this type of individual is a matter of every-day experience. In regard to the association of high tension with arteriosclerosis it is the first which is the cause, the latter being the effect. The triple association of hypertension, arteriosclerosis, and contracted kidneys, as seen in its most typical form in lead poisoning, is obscure and by exclusion the author would attribute it to a neurosis of the autonomous nervous system, which inferentially is present in plumbism. Fleischmann's speculations are suggestive in a way, but they lead to little that is of practical value in the way of prevention or correction of high blood pressure.

A Remedy for High Blood Pressure—Blumenthal describes in the *Muenchener medizinische Wochenschrift* of November 6, 1925, a formula for the treatment of essential hypertonia, the composition of which is as follows, sodium chlor-

ide, 6 parts, sodium nitrite, 20 to 40 parts, sodium phosphate, 3.6, potassium phosphate, 2, and water to make 1,000 parts. This may be injected subcutaneously or intravenously but may also be taken internally. Injections should be made about every other day and apparently should be kept up as long as there are any disagreeable subjective symptoms. There is a sharp fall of blood pressure after an injection but it is not maintained for more than a few hours. The subjective benefit on the other hand will be maintained for one or two days. This consists in the relief of headache, vertigo, shortness of breath, and other disagreeable symptoms. Patients who have taken the treatment for several weeks speak enthusiastically of their improved condition. The benefit must of course be due essentially to the nitrate, yet this drug of itself will not produce the same lasting effects.

Irradiation of the Spleen in Bronchial Asthma—In an article on this subject, published in the *Archives of Internal Medicine* for November, 1925 (xxxvi, 5), George L. Waldbott discusses first the rationale of the method. He presents a review of the literature suggesting that there is a definite relationship of the lymphatic system, of which the spleen is a part, to anaphylaxis. Hektoen has shown that the removal of the spleen reduces the power of an animal to produce antibodies, whereas irradiation of the spleen seems to increase the antibody titer of the blood. On the bases of these results, the author undertook clinical studies on a small number of asthma patients. Under roentgen-ray treatment of the spleen most of these patients improved, and in one case the results were particularly striking. This patient, a boy of 6½ years, who gave positive skin tests to milk, casein, whole egg, and wheat, received one roentgen-ray treatment of the spleen. The dosage administered was 6 minutes, 5 milliamperes, 4 mm aluminum, 88 kilowatts, 10 inches skin target distance. In addition the patient was kept upon an anti-anaphylactic diet for a period of two weeks. The result was entire relief from the clinical manifestations of the disease during a period of eight months. The blood calcium rose slightly, the eosinophile cell count decreased, and the skin tests became negative. Bilateral root infiltration, as shown by the roentgenograms, did not change on repeated examinations after the treatment. Two German writers, F. M. Groedel and H. Lørsen, report that in 71 cases of bronchial asthma in which roentgen-ray treatment of the spleen was resorted to, the results were questionable in 10 cases, negative in 7, good in 15, very good in 12, and splendid in 27. The subject is one which calls for further investigation.

Ultraviolet Light and the Antiscorbutic Vitamin—Investigations have been made by Philip Eggleton and Leslie J Harris (*British Medical Journal*, November 28, 1925, ii, 3387) of the effect of mercury vapor or other light (a) on the synthesis of vitamin C in the plant, (b) on animals kept on a scorbutic diet, (c) on animals already with scurvy, (d) on rations with partly destroyed vitamin C, and (e) on rations rich in vitamin C (a) Light was found not necessary for the synthesis of this vitamin in germinating grain, contrary to the former supposition and in distinction from vitamin A, which is said to require light for its formation in the plant (b) The direct exposure of an animal on a scorbutic diet to ultraviolet light did not appreciably retard the onset of scurvy (c) Ultraviolet light appeared to have no curative action on a scorbutic animal (d) Cabbage in which the C vitamin had been largely destroyed by heat was exposed to the mercury vapor lamp and tested for regeneration of the vitamin, with doubtful results (e) Exposure to ultraviolet light of an infant's food already rich in vitamin C gave no evidence of an augmented antiscorbutic value. These results indicate that while the effects of a deficiency of fat-soluble vitamin in, for example, an infant's diet can be remedied to some extent by exposing the infant (or the food) to sunlight, if scurvy is to be prevented there must be an adequate amount of vitamin C in the diet

The Jaensch Visual Phenomenon.—Karger discusses from the pediatric viewpoint this recent discovery which thus far has received but slight consideration. The constitutional peculiarity is as follows, a certain percentage of school boys in the prepubertal years, when asked to gaze fixedly at various figures held against a black background, are found to be able, after the removal of the figures, still to perceive them in their original locality on the same background. They describe them in their original detail and satisfy the experimenters that neither memory nor imagination plays any rôle in the phenomenon. Jaensch terms the visual object a "subjective-optical gazing image," which is wholly unlike the ordinary after-image. The discoverer goes much further than the mere visual anomaly for he brings it into necessary association with a certain physico-psychical constitution which he terms the "eidetic." The children who show this peculiarity are of the dreamer type and apparently this persistence of images stands in some relationship with intellectual peculiarities such as the persistence of ideas with a resulting unresponsiveness to new mental impres-

sions. Moreover these subjects show endocrine peculiarities and incline to hyperthyroidism or to tetany, there being two opposed clinical types. The phenomenon tends to disappear spontaneously and rapidly at puberty and Jaensch even claims that by giving thyroidin or calcium lactate—according to the type of patient—he can cause the premature disappearance of the phenomenon. Karger, who has gone over the same ground as Jaensch, regards the peculiarity as a remarkable discovery in itself, but as for standing in any necessary association with mental or physical peculiarities he remains wholly skeptical. In no case was he able to modify the phenomenon by the administration of drugs—*Klinische Wochenschrift*, November 19, 1925

The Sugar Treatment of Epilepsy—Wladyczko, a neurologist of Warsaw, refers to the claim that in epilepsy there is a lessened content of blood sugar both under ordinary conditions and under the provocative exhibition of extra diet sugar. He believes that if this lowered sugar content is not the leading cause of the seizures it is at least a contributory factor. Apparently, however, he would not exhibit the sugar without formal blood control, but with reduced content he would give sugar even if the patient were under treatment with the ordinary drugs. He mentions 23 cases in which he gave the treatment with improved spacing of the fits and five more in which the degree of improvement was striking. Sugar may be given in any way so long as the patient receives at least 20 grams daily—in tablets, syrup, or even in the form of the sweet fruits—figs, dates, etc. Tests should show that the hypoglycemia is brought up to the normal by the ingested sugar—*La Presse Médicale*, November 7, 1925

The Oligodynamic Action of Metals—Voight discusses the paradoxical property through which apparently insoluble metals can exert a dynamic action on microorganisms and tissue cells. The data are sometimes cited as a document for the action of "infinitesimals" in medicine. We know that not all metals possess this action. It is seen in silver and mercury but not in gold, and any question of the colloidal state of matter can be ruled out of consideration. The only valid hypothesis involves the belief that in some metals a minute fraction undergoes a change and becomes soluble. The author made some experiments by treating a drop of mercury with gelatin and formol with the apparent result that a definite although very minute amount of the metal passed into a state of solution—*Klinische Wochenschrift*, December 10, 1925

GOVERNOR'S MESSAGE

GOVERNOR ALFRED E SMITH'S OPINIONS REGARDING LEGISLATIVE MEDICAL TOPICS

Extracts From His Annual Message, January 6, 1926

ILLEGAL PRACTICE OF MEDICINE

I renew the recommendation of a year ago that careful consideration be given to the protection of the people of the State from unlicensed and unqualified persons practicing medicine. The co-operation of the medical profession is an essential factor in the protection of the public health, as well as in the care of the sick. A very large part of modern public health is urging people to get the advice of their physicians before serious and perhaps incurable conditions have developed. Such effort comes to naught if unqualified persons are allowed to hold themselves out as physicians.

The subject is a difficult one, but the State of New York should take the lead in establishing high standards of medical practice and providing a practicable plan for their enforcement. It is a matter of justice to qualified physicians and of protection to the public.

CRIPPLED CHILDREN

Last year I called the attention of the Legislature to the necessity of better provision for the care and treatment of crippled children. The present machinery available for this purpose consists of one orthopedic surgeon and thirteen nurses in the State Department of Health and the New York State Orthopedic Hospital for Children at West Haverstraw, for which funds have been made available from the fifty-million-dollar bond issue for increased bed capacity and improvement to the building.

A law was enacted by the last Legislature providing for co-operation between the Departments of Health, Education, Labor and Charities for the care, treatment, education and rehabilitation of cripples. The powers and responsibilities conferred by this law are broad enough, but the small sums granted by the Legislature to the Education and Health Departments were entirely inadequate for carrying them out.

A large part of the work for crippled children is being carried on in the rural districts and smaller cities by private contributions from individuals and fraternal and social organizations.

When it is recalled that there are not less than 12,000 crippled children and young adults in the State scattered over a very wide area, many of whom are most difficult to reach, it must be obvious that the machinery provided for rehabilitating this class of future citizens—most of whom by proper care, treatment and education may be re-

stored to lives of usefulness and happiness—is by no means adequate. Under the appropriation made to the Department of Education a tabulation and analysis of a large number of cripples is now being made. It is to be hoped that the knowledge thus afforded of the location and individual needs of these unfortunates may form a basis for legislative action, including financial provision for their proper care, treatment, education and training.

PUBLIC HEALTH ACTIVITIES

The State of New York unquestionably leads the country in human welfare activities and has reason to be proud of them. To public health, institutional care, conditions of employment, education, housing, recreation, child welfare, and the rehabilitation of the unfortunate, we have given of our best and should continue to do so in full measure.

One of the great functions of government is the preservation of public health. Our State Health Department has established the slogan, "Within certain natural limitations public health is purchasable." No expenditure of public funds brings greater return to the State and its people than the money used for the promotion of the public health. Prevention of disease is cheaper than its cure or long extended care and support.

PUBLIC HEALTH LABORATORIES

Our public health laboratories have been of great assistance in the prevention of disease and are an index of the character and extent of the whole field of public health work throughout the State. There are now 106 approved laboratories in various parts of the State. Since 1923, when the first appropriation was granted for State aid to local public health laboratories, the amounts expended by the State to meet local appropriations have increased yearly and the standards of work have steadily advanced. It is to be hoped that many other localities of the State will take advantage of State aid and increase this very necessary service.

COUNTY HEALTH ADMINISTRATION

I feel compelled to call your attention to a weakness in our present health administration, under the law which has been in existence since the reorganization of the State Health Department in 1914. The present unit of local health administration is entirely too small for efficient

work. It is carried on by general practitioners of medicine in small localities, who, with totally inadequate compensation, are endeavoring to the best of their ability, and with the comparatively short time which they can devote to public health work, to discharge the duties required of them by the Public Health law, and it is due to the unselfish devotion of the great majority of local health officers and their cooperation with the State health authorities that so much has been accomplished.

The unit for local public health work should be the county, with a full-time qualified county health officer who should be made responsible for the conduct of local health matters within his jurisdiction, with only such supervision as the State may be required to give in an advisory capacity. Such an organization has been possible under the law for several years, yet only one county—namely, Cattaraugus—has seen fit to take advantage of it, and with the very best results in promoting the physical welfare of the inhabitants. Other States have made notable progress in county health administration and there are now some 250 such organizations throughout the country.

It should also be noted that under the act providing State aid for rural counties, counties which establish a county health organization may receive from the State one-half of the amount appropriated by the county boards. This need not be an expensive service to the local community, and it is to be hoped that in the near future more counties will avail themselves of the provisions of these two laws which mean so much to the promotion of public health.

CARE OF THE INSANE

The State has also made important advances in the medical care of patients. A medical survey has been made during the past year by a subcommittee of physicians appointed for the purpose. The committee reported its findings and recommendations to the commission and they have been adopted and put into practice as far as possible by the superintendents of the several State hospitals. One of the important improvements in this direction is the establishment at State hospitals of diagnostic clinics. The hospitals have been fortunate in securing various specialists to aid the medical staffs in this work. Through research undertaken in the Psychiatric Institute, and at the State hospitals marked gains have been made during the past year in the treatment of general paralysis. This new treatment gives hope to many hundreds of patients with this most serious mental disorder, and at the present time there are a number of persons suffering from this hitherto hopeless disease who have returned to their homes and are self-supporting and revealing no mental symptoms. Other equally promising gains are being made at other State hospitals, and every effort is being made to keep

them abreast of the best medical knowledge of the time.

A survey has also been made of the State Hospital Schools of Nursing. Many of the recommendations made as a result of the survey were adopted and are being put into effect, but some of the recommendations must await the construction of new homes for nurses and attendants which are being planned as part of the general building program of the State hospitals.

Occupational therapy and physical training are found most helpful and this work is being extended rapidly under adequate supervision.

Under the reorganization amendment the activities of the State in behalf of the insane and those in behalf of the feeble-minded are brought together in one department which will deal with all phases of mental hygiene. At present both the State Hospital Commission and the State Commission on Mental Deficiency have a series of clinics operating in some fifty different localities. Under the reorganization an effective co-ordination of these opportunities for making expert advice and assistance available to persons still living in their own communities and carrying on their ordinary duties can be brought about. Herein lies the great opportunity of the future in mental hygiene.

PREVENTION OF INSANITY

The expenditures of the State for hospital care of the mentally disturbed and the mentally defective is enormous. The loss of earning power to the community is also enormous. The only hope of reducing this tremendous public burden is through an extension of well-considered mental hygiene activities to the various localities of the State. Highly expert advice and treatment is available to the 50,000 persons in the State institutions, but to only a small part of those who would profit by such help if it were available at a much earlier period to persons who are still living in their own homes and trying to live up to their obligations and opportunities in the community. It is only through the extension of such services that we can look forward to any considerable relief from these burdens.

Last year I gave my strong approval to a considerable increase in the number of physicians in the State hospital service, which made possible both increased medical service for the patients in the hospitals and increased clinic service for those outside. This year I would recommend that special consideration be given to providing a larger number of social workers on the staffs of the State hospitals in order to carry on the most important work of aiding individuals and families in getting the greatest benefit from the preventive treatment outlined by the doctor at the clinic.

At present the number of social workers of the State hospitals is barely sufficient to look after

Under the reorganization an effective coordination of these opportunities for making expert advice and assistance available to persons still living in their own communities and carrying on their ordinary duties can be brought about. Herein lies the great opportunity of the future in mental hygiene.

PREVENTION OF INSANITY

The expenditures of the State for hospital care of the mentally disturbed and the mentally defective is enormous. The loss of earning power to the community is also enormous. The only hope of reducing this tremendous public burden is through an extension of well-considered mental hygiene activities to the various localities of the State. Highly expert advice and treatment is available to the 50,000 persons in the State institutions, but to only a small part of those who would profit by such help if it were available at a much earlier period to persons who are still living in their own homes and trying to live up to their obligations and opportunities in the community. It is only through the extension of such services that we can look forward to any considerable relief from these burdens.

Last year I gave my strong approval to a considerable increase in the number of physicians in the State hospital service, which made possible both increased medical service for the patients in the hospitals and increased clinic service for those outside. This year I would recommend that special consideration be given to providing a larger number of social workers on the staffs of the State hospitals in order to carry on the most important work of aiding individuals and families in getting the greatest benefit from the preventive treatment outlined by the doctor at the clinic.

At present the number of social workers of the State hospitals is barely sufficient to look after

the patients on parole, leaving little or no time for the real preventive work. A Director of Social Service should be made a member of the staff of the State Hospital Commission, and, later, of the State Mental Hygiene Department, in order that this work may be properly coordinated.

MENTALLY DEFECTIVE CHILDREN

As is now generally recognized, the greatest opportunity for forestalling mental ills lies in work for children. The State is already giving financial aid to localities in the operation of special classes for backward children in the public schools of the State. As yet, however, the larger part of the backward children who need the training that a special class can give them are not receiving it because many communities are entirely without special classes, and most others have not organized a sufficient number of them. In the even more important work of skilled treatment for the so-called "problem children," who are emotionally disturbed, our public schools are doing very little.

The time has come, I believe, to organize in the Department of Education a special Bureau of Mental Hygiene headed by a competent psychiatrist, where responsibility may be centered for organizing mental hygiene work for all types of children with mental difficulties. Such a bureau should cooperate closely with the State mental hygiene agencies, and take advantage of all the facilities, clinical and otherwise, which they can place at the disposal of the public schools.

OCCUPATIONAL DISEASES

As the law and court decisions now stand, compensation can be awarded for many of the diseases of employes due to occupation. For some others it cannot. There is an element of injustice in this situation. There is no fundamental reason of equity for any such distinction between disabilities due to diseases which are caused by occupation. The line now drawn seems to be largely arbitrary so far as principle is concerned and only the result of legislative compromising.

Equal treatment under the law is the proper remedy for this situation. On general principles all diseases arising out of and in the course of employment should be made compensable. There is good precedent for this all-inclusive remedy in the laws of several of the other States which have had it for a number of years.

There is no reason to believe that such an extension of coverage would involve any considerable increase in the total costs of compensation. The more common occupational diseases are now specifically covered in our law or have been held

compensable within the definition of accidental injuries, so that to cover all diseases due to occupation, as all accidental injuries due to occupation are covered, would not entail any undue burden on industry.

LOSS OF VISION DECISIONS

A recent decision of the Appellate Division has completely overturned the practice that prevailed since the Workmen's Compensation law was enacted with reference to the test to be applied in determining the percentage of loss of vision. The result is that there is confusion and uncertainty as to just what element should be taken into consideration in determining the percentage of loss of vision. Moreover, the decision of the Appellate Division, if carried to its logical conclusion, will result in less compensation for eye injuries than was intended when the schedule loss of 160 weeks' compensation for the loss of an eye was enacted.

To remedy this situation the Legislature should prescribe a standard method to be adopted in disposing of eye injuries or else confer power on the Industrial Board to do so and in conformity with such test should amend the law so as to provide for adequate compensation to the victims of such accidents.

BOVINE TUBERCULOSIS

Our Department of Farms and Markets is concerned not alone with helpful suggestions to the farmer but in the exercise of what might be called the police power for the eradication of plant and animal diseases. Chief among all is the eradication of bovine tuberculosis. I am informed by the Commissioner of Farms and Markets that in 1925 the greatest progress in the elimination of this disease in the herds of our State has been attained, surpassing anything accomplished in any year since the work has been in progress. During the past twelve months over 50,000 herds containing nearly 600,000 cattle have been subjected to a tuberculin test and all tuberculous animals eliminated. Considerably more than one-third of the townships of the State have been completely tested.

It is gratifying to note the advance made in a few years when the reputation of New York cattle had fallen so low that many of the States of the country had quarantined against us. In my message of last year I stated that in my opinion our low death rate was due to the care exercised by the State in ridding the herds of the State of tubercular cattle, and the work must be carried on as speedily as the department is able to do it properly.

State Department of Health

One Death From Rabies, Another From Transverse Myelitis Following Pasteur Treatment

During the early part of 1925 rabies in dogs became prevalent in Westchester county. Several persons were bitten and took the Pasteur treatment. One of these, a boy of five, was severely bitten on the face on March 26. The wound was treated with iodine and alcohol and eight sutures were taken. Pasteur treatment was begun on the next day, a total of eighteen injections being given. On April 12 this child developed dimness of vision, difficulty in swallowing, drowsiness and drooling. The temperature was 100 degrees F and the pulse, 140. He died from rabies at the Willard Parker Hospital, New York City, on April 14.

A death from transverse myelitis in a man 57 years old was reported in October. On May 22nd, the patient had been bitten on the hand by a rabid dog. The wounds were cauterized (?) and Pasteur treatment was begun on May 26th. A total of fourteen treatments had been given up to June 10 when a right-sided paralysis appeared, involving the leg and extending to the nipple line. Within a few hours the left side was similarly involved, with accompanying paralysis of the sphincter muscles of bladder and rectum. The paralytic symptoms lessened and the patient was encouraged to sit up in a wheel chair.

On August 15 areas of breaking down tissue developed over the hips and sacrum. The necrotic areas were deep seated and were covered with apparently normal but superficial layers of muscle and skin. Upon operation necrotic masses about two or three inches in diameter were removed. Later there were localized gangrenous areas on the feet and legs.

The cause of death was given as transverse myelitis of the lower extremities, contributing cause, toxemia from gangrene. In this case there was no known or probable history of syphilis and the urine was sugar free. Alcoholism could be ruled out and the patient received no blows or falls during the course of treatment.

Serum Therapy in Erysipelas

Older clinicians are divided in opinion as to the value of anti-streptococcus serum in erysipelas, into those advocating strongly its use in this affection and those who have not seen much beneficial effect from it. It seems of interest in this connection to draw attention to a recent series of articles by Birkhaug on the biology of the streptococcus erysipelatis*. This author amplifies the findings

of other workers, as regards the specific agglutination and opsonin reactions of streptococci isolated from cases of erysipelas, by demonstrating that an immune erysipelas rabbit serum has a specific and definite neutralizing and protective action in these animals against the injurious effect of the streptococcus erysipelatis.

Clinical application of these findings has been made by Birkhaug. The serum, when injected intracutaneously into the erysipelas rash of a patient, causes soon afterwards a fading of the lesion, with disappearance of the edema and tenderness. It is claimed that the action of the serum in this respect was specific. It is stated further that promising results were also obtained with intravenous and intramuscular administration of large doses of the immune serum in several cases.

Definite results in the practical applications of serum therapy will be needed in more cases for confirmation, especially in view of past experience with the use of anti-streptococcus serum in the streptococcus infections, which are predominantly parasitic. The observations of Dr. Birkhaug, are, however, extremely interesting and suggestive.

Botulism or Strychnine Poisoning

Recently there came to the attention of the Department the death of a three year old girl from botulism. The case was investigated with interesting results.

It was found that the girl was dead when the physician arrived, her brother who had similar symptoms was in convulsions but recovered in about three days, treatment consisting of a hot bath, morphine, an emetic and enemata later bromide and chloral. The evacuations following the enemata contained a large amount of undigested corn and a reddish substance believed to be salmon. According to report the corn had been eaten green. The report did not state whether or not other members of the family had partaken of the same food as the children.

It was reported that the mother (who was away at the time of the investigation) had stated that the children had been playing with strychnine tablets. Although the grandmother denied that the children had found any such tablets the nurse stated that when she first saw the girl immediately after the onset of the illness consisting of convulsions, the child was absolutely rigid with slight opisthotonos. When placed in a hot bath she had twitching of the hands, legs and feet. She died fifteen to twenty minutes later.

From the history and the description of the symptoms—the case was not one of botulism but resembled strychnine poisoning.

Heredity vs Training

Can any child that might be chosen by lot be trained so that it will be a paragon of ability, virtue, and morality? An editorial in the New York *Herald-Tribune* of December 23, entitled "A Comfortable Psychology," raises this question. The editor quotes a psychologist as saying

"I would feel perfectly confident in the ultimately favorable outcome of careful upbringing of a healthy, well-formed baby born of a long line of crooks, murderers, thieves, and prostitutes—to become any type of specialist I might select—into a doctor, lawyer, artist, merchant-chief, and, yes, even into beggarman and thief, regardless of his talents, penchants, tendencies, abilities, vocations, and race of his ancestors."

This is a sweeping statement, and possibly the psychologist could instill permanent virtue into a badly born child by the exercise of almost superhuman oversight and prescience. However, the *Herald* editorial writer wisely differs with him and says

"Every man likes to think that he might have done other things as well as the things he has done. The merchant, for example, likes to think not that he has not become an artist because he could not, but merely because the same man cannot become too many different things at one and the same time. It is true that any man can do the rough work of any trade. Amateur plumbers, carpenters, masons, painters, sometimes do fairly well. But for work of the best class, something more than amateur versatility is needed. And so it is in all occupations and professions. Within limits, any man can do anything, but the limits are soon reached, and for the achievement of the highest excellence we are still constrained to believe that something more than ordinary good health and training are necessary."

Physicians believe most thoroughly in the effects of environment and the value of training on the mental and moral natures. They are the basis of the prevention and cure of insanity and crime. But consider the age at which training begins. A child has had nine months of prenatal development and a year or two of growth after birth before what we call the mind is developed sufficiently to be susceptible of training. Growth during all these months and years of preinfancy and infancy life is governed by what the child has received from its parents—that is, by heredity.

Heredity gives the child two mental characteristics, 1, mental capacity, including talents along certain lines, and 2, temperament, including emotional trends. Natural talents and emo-

tional trends must be considered in the training of every child. These characteristics may be foretold with some degree of probability early in life only by a study of the mental characteristics of the parents and ancestors for several generations. If a teacher knows the probable mental characteristics of a number of children, he may be able to develop desirable traits and suppress those undesirable by intensive individual training, but he will be likely to fail in a considerable proportion of his prognostications, and therefore he will also sometimes fail to produce a highly desirable type of adult.

It is a popular belief that the mind is implanted in the unborn child only a short time before birth, and that a fright of the mother or a premature birth may prevent the implantation of the child's mind. This is a comfortable theory to account for the mental state of an imbecile child. The older systems of theology teach the possibility of a new birth of moral characteristics in adult life, but even the church admits the persistence of the former yearnings, and takes great pains to guard the newly implanted spark of spirituality lest the hereditary tendencies of the old Adam again assert themselves.

This is a practical age, and physicians are optimists regarding therapeutic and preventive measures to secure mental and moral health. They must take their patients after hereditary influences have done their work, and the best they can do is to uphold and apply all efforts in securing proper environment and training for all children, especially those whose hereditary influences have wrong tendencies.

Religious Training and Moral Health

Physicians believe that religious training is the most potent of all influences in promoting moral health. The newspapers lately have printed the remarks of physicians and scientists regarding the great need that the Church and Sunday-school shall reach the young people and shall impart to them high moral ideals. An example of such a news note is contained in the *Herald-Tribune* of December 30th in reporting the remarks of Dr. Frederick L. Hoffman, Secretary of the section of Social and Economic Sciences of the American Association for the Advancement of Science. Speaking in a session of the Association at Kansas City, Dr. Hoffman said

"Perhaps the greatest force in combating and reducing crime is the re-creation of a sense of answerability to God. That sense is becoming vague, shadowy. But it is the knowledge of God that makes one think twice before committing a

criminal act, for religion of all things profoundly affects man's life and awakens a sense, an urge, toward the normal, the orderly."

The Brooklyn *Eagle* of November 29th expresses the same idea in a letter by Dr John F. W. Meagher, who won the prize offered by the newspaper for the best suggestion for the solution of the crime problem. Dr Meagher says

"The three chief barriers against crime are conscience, religion, and the law—moral ideas and right conduct being the basis of all three. Through the agencies of the home and the church there should be developed an idealistic desire for right thinking and right living. Inasmuch as the greatest social relationships are formed during adolescence, *it is at this time that religious instruction should be intensive.* The parents should set a good example in this respect. This is doubly important when one remembers that the maximum age period for crime against the person is 18 to 21 years. Religion, however, must be imparted and accepted by the heart and not verfunctorily. Eighty per cent of habitual criminals have had no real religious foundation."

The New York *Herald-Tribune* of January 3rd comments on the annual report of Dr Nicholas Murray Butler, President of Columbia University, to the Board of Trustees, in which he ascribes the cause of crime to ills of education. After discussing the broad cultural value of a liberal education and the place of specialization in college studies, he takes up the religious phase of university education, and says

"Throughout the nation there is obvious and often expressed concern over the widespread lawlessness that has attracted the attention of the whole world. This lawlessness has causes that lie far deeper than most present discussion would seem to realize. The multiplication of courts and the infliction of more severe sentences upon offenders would not affect the prevailing lawlessness in the least.

"This law-breaking habit has grown up through lack of discipline and self-discipline, through lack of real education, and it will not be checked or overcome until these deficiencies are repaired. Law-breakers are almost uniformly graduates of our common schools and not infrequently of our colleges as well. This fact tells the story. They have not been disciplined, trained, educated, either at home or at school or at college, to those habits of self-control, self-mastery, and self-direction which are the only effective protection society has against law-breaking and lawlessness.

"The college has a clear duty in the religious instruction of the students. It would be quite as unreasonable to exclude religion from the college curriculum as it would be to exclude literature, or science, or the fine arts, or the study of the ethical and institutional life of man."

Since physicians and scientists recognize the great power of the church in promoting mental and moral health, physicians and ministers should devise some method by which they can get together and cooperate in the prevention of crime and other forms of immoral conduct. Physicians and especially those who practice psychiatry, are impressed with their duty to solve the medical and psychological phases of mental and moral pathology, and church leaders are charged with the care of the spiritual and religious phases of conduct. Physicians and church leaders reach every hamlet in the land, but each group is working largely independently of the other, thereby missing the fullness of its opportunity. Religious leaders need to gain an insight into the scientific phases of mental medicine, while physicians need to recognize the compelling power of the spiritual influence of the religious leaders. Each group should minister to the mentally sick in his own way, and at the same time give full credit to the therapeutic measures applied by the other. Much of the potency of the doctor's pills are due to the comforting influence of his unconscious spiritual ministrations, and on the other hand, his pills help to remove the depressing toxins from the blood, and so prepare the soil for the spiritual seed of the religious worker.

Rehabilitation of the Convict

The cure of the criminal was discussed by Lewis E. Lawes, Warden of Sing Sing Prison, in a speech before the *State Conference of Charities and Correction* reported in the December 15th issue of the *New York Sun*. The warden said

"The causes of crime lie too deep for mere punishment ever to reach them. Crime is increasing for much the same reason that divorce is—the latter showing an increase of 118 per cent, according to recent statistics, for the country as a whole. Home life is a thing of the past, and our social structure in all its branches is drastically weakened."

"We recognize to-day that not only are individuals responsible to society but that there exists a grave reciprocal responsibility on the part of society to the individual. In numerous instances the crime is but the natural result of the environment in which the offender was brought up. It may be a case of total illiteracy and ignorance, of a childhood spent in the slums, in crowded filthy tenements, under conditions which make modesty, physical and moral cleanliness unknown and impossible."

"We are coming to a new viewpoint, that society is better protected (and punishment is but a device to enforce protection) by the rehabilitation of the offender, and that it is very difficult, if not impossible, for the judge to know in advance how long a time will be required for such social readjustment."

BOOK REVIEWS

RHEUMATIC HEART DISEASE. By CAREY F. COOMBS, M.D., F.R.C.P., London. Introduction by F. J. POYN-
TON, M.D., F.R.C.P., London. Numerous original
plates and illustrations. William Wood and Co,
N. Y., 1924. Price, \$4.50.

Coombs' "Rheumatic Heart Disease" is a noteworthy monograph on a subject of tremendous importance. He believes the diplo-streptococcus of Poynton to be the causative virus, but fails to clearly differentiate it from the streptococcus anhemolyticus of Schottmuller, now almost universally believed to be the cause of most cases of subacute bacterial endocarditis.

The thorough discussion of the pathology and symptomatology of the various manifestations of the disease as it affects the heart must be read to be appreciated. Valuable data for the proper prognosis is given. Treatment both prophylactic and curative is thoroughly discussed—stress being laid on the importance of rest and later graded activity with constant supervision and guidance.

The book is a distinct contribution to the further understanding of this most formidable disease, and can be highly recommended to the general practitioner. Its style is pleasing and is written by a master of his subject.
MEYER A. RABINOWITZ

VAGOTONIES, SYMPATHICOTONIES, NEUROTONIES. Les Etats de Desequilibre du Systeme Nerveux Organo-Vegetatif. By Dr A. C. GUILLAUME. Octavo of 281 pages. Paris, Masson et Cie, 1925. Paper, 14 fr.

This work includes a comprehensive survey of the etiology, clinical aspects and treatment of the disturbances of the vegetative nervous system. In his work, the author has largely followed the well-known classification of Eppinger and Hess, which he has modified somewhat to suit his views. The close relation of the neuroses to disturbances of vagal and sympathetic tone is well exemplified.
FREDERIC DAMRAU

DISEASES OF THE EAR, NOSE AND THROAT. By HAROLD HAYS, M.A., M.D., F.A.C.S. 495 Half-Tone and Line Engravings, 55 Full Page Plates. F. A. Davis Co., Philadelphia, 1925. Price, \$10.00 net.

Among the recent text-books on diseases of the ear, nose and throat, this one by Dr Hays may be said to have filled a gap for the student and general practitioner. The medical aspect of this specialty is sufficiently emphasized and just enough technique is supplied to acquaint the reader with some of the commoner surgical procedures in oto-laryngology. Such was the aim of the author, and it has been fully carried out.

More than half the book is devoted to Otolaryngology. A special chapter on Diphtheria is written by the noted otolaryngologist, Dr Louis Fischer of New York. Dr Isaac Meigs of Los Angeles has written the chapter on the diagnosis of the upper air passages and Oesophagus by the laryngoscope. The text is concluded by a chapter on the development of the upper air passages and Oesophagus by birth and infancy. There are no less than fifty-five full page plates, nearly all of which are original. One rarely sees a text-book with such during colored plates. The plates on drum membrane and infarct are highly instructive.

The book in many instances does not lend itself to the same degree of emphasis on the treatment as given him the best results in practice. There is too much manipulation in cases of foreign bodies in the external canal. In at least 99 per cent of cases it is all that is necessary, except in the emotions that swell, as peas and beans. The

legal importance of previous attempts at removal by others should not be forgotten.

The chapter on Progressive Deafness has food for the specialist and student.

The value of transfusion in sinus thrombosis, septic ear cases and in cases of double mastoiditis with suspicion of sinus thrombosis cannot be too strongly emphasized.

The use of autogenous vaccines is advocated in chronic nasal catarrh with no pathology. The majority of men find very little benefit from their use.

The section on chronically diseased tonsils is well written, especially examination and indications for operation. Palpation of tonsil region is advocated. The author calls attention to the presence of encapsulated abscesses beneath the capsule of the tonsil. They appear as yellowish areas which may be situated anywhere in the tonsil parenchyma and has nothing to do with cryptic pathology. This is always an indication for operation.

B. H. ABRAHAM

LES ARYTHMIES EN CLINIQUE PAR A. CLERC, PROFESSEUR AGREGÉ A LA FACULTE DE MEDECINE. MEDECIN DE L'HOPITAL LARIBOISIERE. Preface du Pr H. VAQUEZ. Masson et Cie, Editeurs. Paris 1925. 34 fr.

In this volume the author has given a very accurate description of all the cardiac arrhythmias, but the special value of the book lies in his correlation of experimental and graphic study of these disturbances, with the clinical features.

The presentation of each cardiac irregularity begins with graphic studies in which numerous curves of the radial pulse, apex beat, venous pulse, polygrams and electrocardiograms are given and described. Then follow the testimony of experimentation, the pathological anatomy and the mechanism of each arrhythmia and finally a clinical study of the etiology, symptomatology, prognosis and differential diagnosis of each disturbance. There are also special chapters devoted to descriptions of the various graphic methods of study of the heart beat, to the pharmacology of the drugs used in heart disease and to the treatment of the cardiac arrhythmias.

The author draws freely from the best work of French, German, English and American cardiologists, especially from Sir Thomas Lewis for his description of the arrhythmias, but the feature of the work that makes it a real contribution to cardiology is the systematic presentation of the wealth of careful clinical observation that it contains.

EDWIN P. MAYNARD, JR.

AN INTRODUCTION TO THE MIND IN HEALTH AND DISEASE. For Students and General Practitioners Interested in Mental Work. By WADDELOW SMITH, F.R.C.S. (Eng.), Deputy Medical Superintendent of the City Mental Hospital, Nottingham. William Wood and Co., New York, 1925. Price, \$4.00.

The author ranges over a wide field, or fields, and touches the high spots here and there. He discusses neurology, including anatomy, physiology, histology and embryology of the nervous system, psychology, endocrinology, psychiatry, psychoanalysis, feeble-mindedness and sexual anomalies. To neurasthenia he devotes one page, to hysteria and war neuroses, two and one half pages. The book is made up largely of definitions, which is about all that the space will permit of. As an introduction it is too brief and condensed. It might serve for a hasty review of the subjects touched upon.

PROSTATIC OBSTRUCTIONS IN PATIENTS OVER 50 YEARS OF AGE

By DAVID M DAVIS, M D,
ROCHESTER, N Y

THE purpose of this paper is to present the subject of prostatic obstructions in men of advanced years, not from the point of view of surgical treatment only, but considering the condition as it arises in daily medical practice, with regard to the diagnosis, treatment, and prognosis at all stages of its progress

In the early stages of a prostatic obstruction, the clinical picture usually embraces little more than the single symptom of frequency of urination. This symptom is indeed so common that even the laity are accustomed to regard getting up once or twice at night as a necessary evil, after passing a certain age. While apparently in a number of cases the frequency never becomes greater than this, and no other bad effects are felt, yet it is by no means always so, and the physician must be alert to guard against urinary infections, diverticula and stones in the bladder, renal insufficiency, and uremia, which occur in cases where the obstruction is a progressive one. For example, one man visited his physician because a rapidly enlarging abdomen necessitated the frequent purchase of new trousers. There was no urinary frequency. Catheterization revealed a residual urine of 2000 c.c. This sudden emptying of the bladder resulted in uremia, and the patient's recovery was in doubt for many days. Another sought medical advice because of a sudden increase in frequency and difficulty after four years, during which he had arisen to void four or five times every night. Examination revealed an enormously hypertrophied prostate, with multiple diverticula of the bladder. These became infected following catheterization, and this infection was not affected by treatment, making the patient an invalid even after prostatectomy, and requiring a second arduous operation

for removal of the diverticula. A third individual, with a slight frequency but with residual urine of 600 c.c., died of uremia forty-eight hours after his first catheterization, done only for diagnosis.

In the diagnosis of cases complaining of urinary frequency, the rectal examination, while important, may give wrong impressions unless it is supplemented by certain other procedures. The reason for this is that the degree of obstruction has nothing to do with the size of the prostate. In some cases we find the prostate much enlarged by rectum when there are no urinary symptoms and no residual urine is present. At other times the prostate may feel normal by rectum when a small hypertrophied mass directly in the region of the vesical orifice is causing the most extreme degree of urinary obstruction.

Much may be learned about these early or insidious cases by two simple procedures, both aimed at the discovery of residual urine without the use of any instruments. The first is nothing more than percussion of the bladder. If any bladder flatness can be detected above the symphysis just after the patient has voided, residual urine is present, and it is necessary to take warning. If there is flatness as much as two finger-breadths above the symphysis, the amount of residual urine is large, and active treatment, probably operative, is necessary. If there is flatness three or more finger-breadths above the symphysis, the residual urine is very large, and the patient is in very real danger, which may be increased by a hasty emptying of the bladder by catheter.

If, on the other hand, there is no flatness above the symphysis, one injects one c.c. of the usual phenolsulphonphthalein solution containing 0.6

COLLECTED PAPERS OF THE MAYO CLINIC AND THE MAYO FOUNDATION Edited by Mrs M H Mellish Volume 16, 1924 Octavo of 1331 pages with 254 illustrations Philadelphia and London, W B Saunders Company, 1925 Cloth, \$13 00

The present volume, number 16, contains those papers published during 1924, abridged, abstracted or by title. This plan has been followed for the reason that many are too technical or of limited interest.

The vast and varied amount of material between the covers of this book makes it impossible to comment upon any of the individual contributions. It includes 214 papers by 126 contributors, which should impress all with the considerable work being done by the Staff of this aggressive Clinic.

These papers represent in book form an addition welcome to one's library

THE NATURE OF DISEASE By J E R McDONAGH, FRCS Part 1 Royal octavo of 327 pages with illustrations London, William Heinemann 1924 Cloth, £3 3s

This is one of the most extraordinary books the reviewer has ever read. So remarkable and original are its conceptions, that one is inclined to scepticism, yet so wide is the author's knowledge and so much experimental proof is brought forth that one is forced to concede respectful attention at least. One cannot but be impressed by the magnitude of the experimental work, the extent of the author's interests and his tireless energy.

Starting with research into the action of the spirocheta pallida upon tissue cells, the author is led to study the mechanism of staining reactions, cancer, the electronic behavior of body proteins, bacteria and drugs and finally comes to a new conception of the Wassermann reaction, sensitization and immunity.

Diverse and unrelated as these subjects appear, the author links them together in a truly remarkable concept. The title "Nature of Disease" suggests that these researches are an effort to get at the fundamental mechanisms of disease. Briefly stated, the author believes that disease and immunity reactions are the results of changes in the colloid and electronic states of the body proteins. Metals are conductors of electricity, all other substances, including bacteria, are condensers, varying in degree. The body proteins react to these substances causing changes in colloidal and electronic states which in turn cause tissue changes. To treat disease rationally one must study these electronic and colloidal changes by appropriate tests and use drugs which will restore the normal state. This sounds fantastic but readers who are familiar with physical chemistry will find much food for thought. If McDonaugh's work is confirmed, he will have opened up a new field for research and we will look forward eagerly for further contributions by this remarkable man.

E. B SMITH

MEDICAMENTS ET MEDICATIONS CARDIAQUES By H Vaquez Octavo of 302 pages Paris J B Bailliere et Fils, 1925

This book consists of reports of lectures on the treatment of diseases of the heart by Dr Henri Vaquez to his students, which were taken down by his interne, M. Theodoresco, and brought together in book form. The preface states that Dr Vaquez revised critically the

The scope of these lectures embraces practically the whole subject of cardiac therapeutic. Their style is that of a brilliant lecturer who has something to present. The informal manner in which the subject is presented is particularly pleasing, and compares favorably with the more formal manner of text books. Also, it is evident that the author speaks more freely in these lectures than he would in a formal text book, or than a

did, indeed, in his text book on diseases of the heart published a year ago. It is not too much to say that this book will prove of very great value to the average practitioner of medicine who desires to learn how to treat heart diseases. He will be able to get from it easily and pleasantly instruction by one of the greatest living cardiologists.

Those familiar with Dr Vaquez's writings are aware that he has done much to spread knowledge of the therapeutic value of strophanthus which he considers the "heart medicine par excellence." He has devised a technique for the administration of ouabaine, one of the crystalline strophanthus, which makes it possible to use that powerful remedy in cases of severe heart failure with great advantage.

So great is the practical value of this book that it is to be hoped that a translation will soon place it in the hands of English readers.

E. E CORNWALL

MODERN SURGERY, GENERAL AND OPERATIVE. By JOHN CHALMERS DA COSTA, M.D., LL.D., F.A.C.S. Ninth Edition, revised and reset. Octavo of 1527 pages with 1200 illustrations Phila. and London. W B Saunders Company, 1925 Cloth, \$10 00

This is the ninth edition of this work and its publication celebrates the thirty-first birthday. It is gratefully dedicated to Chevalier Jackson.

The author has tried to avoid writing a preface, but we are glad that he has succumbed and added those touches of humor which we have learned to expect from his pen. He has again revised and reset the bulk of the work himself, but he has received aid from the following Doctors: Chevalier Jackson, Randie C. Rosenberger, Charles F. Nassau, Elmer H. Funk, Thomas A. Shallow, Captain George U. Pilmore, M.C., U.S.N., Willis F. Manges, George E. Pfahler, Thomas Cook Stellwagen, Arthur J. Davidson, Harold W. Jones, Warren B. Davis, Hubley R. Owen and William L. Clark.

The author has wisely decided to omit Surgical Bacteriology, as well as chapters on asepsis and antiseptics and Bandaging.

It is to be hoped that this revision will prove the forerunner of many more to come.

R H F

ESSENTIALS OF IMMUNOLOGY FOR MEDICAL STUDENTS. By ARTHUR F COCA, M.D. Octavo of 194 pages, 16 plate illustrations Baltimore, Williams and Wilkins Co, 1925 Cloth, \$3 50

This volume is a review of the subject of Immunology, written primarily for medical students, but because of its conciseness, also suited to the needs of the physician. The theoretical aspects of the subject are contained in the first eleven chapters, which are condensed into about seventy pages. The style of presentation of material is critical and impersonal, and the author's intimate contact with immunological literature enables him to present the most recent conceptions and developments in the subject. Because of its simplicity and completeness, the chapter on Hypersensitiveness is especially worthy of commendation.

The next one hundred pages, comprising seventeen chapters are devoted to practical exercises. They include descriptions of the technique of various procedures, as the Schick test, Dick test, blood grouping, Widal Wassermann test, etc., together with brief comments as to the value and limitations of each. Two well illustrated chapters are devoted to descriptions of apparatus and general technique, and contain a wealth of practical information for the novice who is embarking on his first ventures in immunological fields. This little volume should prove exceedingly popular with student and physician, because, in it, the author has achieved brevity, without sacrifice of clarity or completeness.

M. W

two or three months in order to detect in their incipency any further complications which may occur

Various forms of treatment have been recommended in such cases where the situation is not urgent. They include prostatic massage, hot or cold rectal irrigations, treatment with ultra-violet light, diathermy, various forms of electric current, radium and X-ray. It may be said of all these forms of treatment that they have apparent-beneficial effects at least for a time, on some cases, but that they cannot be relied upon to effect a cure, or even an improvement in all cases. If it is decided to resort to any one of them, the same watchfulness must be observed so that in case they fail to accomplish any good, this failure will be detected in time to give the patient the benefit of surgical treatment.

If, on the other hand, frequency and burning are sufficient to annoy the patient greatly and deprive him of rest, if the residual urine is more than 100 c.c., if the kidney function is diminished, or if there is any nitrogen retention in the blood, early surgical treatment is indicated.

The results of surgical treatment of prostatic hypertrophy are among the most satisfactory in all surgery, since the danger of the operation is almost negligible and it is one which usually does not only help the patient, but cures him entirely and restores him to good health. In a series of 1,049 cases of hypertrophy of the prostate operated upon in Baltimore by Dr. Hugh Young, over a period of 15 years, the death rate was 3.4%. During seven of these years there were no deaths whatever. The cases were not carefully selected and included many who had been allowed to reach a very bad condition before surgical treatment was considered. Other surgeons, who operate upon large numbers of cases of prostatic obstruction, report figures comparable to these, whatever method of operation is used. The great success which these surgeons have obtained, however, is due less to their skill in performing the operation, than to the care exercised in preparing the patients for operation. This pre-operative care is based upon the principle that the obstruction should be relieved by a retention catheter or by a suprapubic cystostomy and that no further operation should be done until, aided by the copious administration of water, the patient's kidney function and general well-being have returned practically to normal. It

has been shown more recently, that, in case the residual urine is large, the above-mentioned relief of the obstruction must not be given suddenly, but, by use of a catheter, the pressure within the bladder should be reduced gradually over a period of days, thus allowing the kidney to accustom itself to working under conditions where there is no back-pressure upon it.

The prognosis in prostatic obstruction depends aside from the general condition of the patient, and the existence of other diseases not connected with the urinary tract, upon the amount of damage done to the urinary tract by the obstruction. Thus, if the obstruction is allowed to proceed for a very long time, the bladder, ureters and kidney pelves become dilated, diverticula develop in the bladder, stones form in the bladder or kidneys and infection usually occurs sooner or later, which may be confined to the bladder or may spread to the kidneys, giving rise to pyelonephritis, with resulting uremia. It is, therefore, an error to consider that surgical treatment is a last resort in cases of prostatic obstruction, since by so doing patients are allowed to reach a condition where their prospects for a successful result from the operation are much diminished. Obstruction should, on the contrary, be removed as soon as it is shown to be definite and unmistakable and at a time before the patient has been injured and weakened by the onset of the complications mentioned above.

In certain cases complications arise insidiously and there may even be very little to point to a urinary obstruction as the cause of the patient's disease. This is especially true when uremia, arterial hypertension, diverticula or stones develop, with no attacks of complete retention or no great dilatation of the bladder. The patient usually suffers from frequency of urination, but this may not be very pronounced and, as stated above, he may neglect for a long time to consult a physician about it. It is always wise to inquire about frequency of urination if the patient does not mention it. The measures described above will usually serve to disclose the presence of the obstruction and they should be applied in all cases having hypertension or uremic symptoms, even if no urinary symptoms are complained of. No male patient, above the age of fifty, should be treated for nephritis until it is definitely ascertained that he is not suffering from urinary obstruction. If obstruction is the cause of his renal

of a gram. This injection is best made intravenously to insure rapid absorption. The patient is instructed to void between 5 and 10 minutes after the injection and again at the end of 35 minutes, 1 hour 5 minutes and 2 hours 5 minutes. He should drink a considerable quantity of water before and during this test in order to assure a plentiful secretion of urine. The red color of the phthalein should appear in the first specimen voided a few minutes after injection. If it does not we may assume that the kidney function has been interfered with in some way. The second specimen, containing the urine secreted in the first half hour, should contain more phthalein than that secreted in the second half hour, while the sum of the second and third specimens, containing the phthalein secreted in the first hour, should be considerably greater than that in the fourth specimen containing the phthalein secreted in the second hour. The sum of all four specimens should be equivalent to what is ordinarily spoken of as the normal phthalein output for 2 hours, namely at least 55 per cent. If the concentrations in the last three specimens are about the same and if the quantity excreted in each is about the same, we may assume either that the kidney function is seriously damaged or that there is a large residual urine in which the kidney urine is diluted and in which a large proportion of the phthalein excreted by the kidney is retained in the bladder, so that we cannot measure it. This simple test, therefore, gives very useful information. If the result is normal we are sure not only that the kidney function is good, but also that there is little or no residual urine in the bladder, since, if there were, a portion of the phthalein would be retained and it would be impossible for the figures to be normal. If, on the other hand, there is a diminution in the excretion of phthalein, serious kidney damage has already occurred and we are, therefore, warned that we must immediately undertake further measures in order to be absolutely certain whether this reduction of kidney function is due to a prostatic obstruction or to a chronic nephritis.

The examination of the urine is usually done first, but it is really of less importance in these cases than the procedures mentioned above. There is nothing characteristic about the urine in prostatic obstruction. It is to be studied principally to determine whether or not infection is present. The urine should always be voided in

three glasses. A portion from the second glass should be centrifugalized and the sediment smeared on a slide, dried and stained with methylene blue. In this way one can determine the morphology of the cells present, determine the proportion of pus cells and also see whether the urine is infected with bacilli, cocci, or both, and the relative number of bacteria present. The specimen is taken from the second glass in order to avoid any contamination by pus or bacteria which may be in the urethra. Study of the urine also discloses other lesions which may sometimes simulate prostatic obstruction, especially tuberculosis.

Any physician can make the above examination easily in his own office and, if he does so, he is in possession of valuable information, which enables him to judge what the needs of the patient are. The important thing is to know not merely that an obstruction is present, but how much damage the obstruction has caused to the patient.

If the physician wishes, he can obtain still further information by catheterizing the patient, which will enable him to determine the exact amount of residual urine present and also the bladder capacity. Two precautions must always be observed, however. The first is to avoid emptying the bladder by catheter when the residual urine is very large, that is to say, when the bladder can be percussed two or more finger breadths above the symphysis immediately after voiding. The second is to avoid infection, which can only be done by observing the most scrupulous asepsis, irrigating the urethra before and after catheterization and leaving in the bladder a small quantity of some efficient antiseptic drug, such as mercurochrome, merocryl or argyrol.

If, however, it is not desired to catheterize the patient, a specimen of blood may be taken, which will reveal whether any nitrogen retention already exists in the blood stream.

Having made these studies, one may be guided by the following considerations. If the frequency is slight and annoys the patient but little, if the residual urine is less than 100 c.c., the kidney function good, the urine uninfected and the blood nitrogen normal, surgical treatment may be delayed. It is necessary, however, to impress upon the patient the importance of complications which may arise so that he will remain under observation. He should be seen at least every

"THE EFFECT OF PRODUCING ASEPTIC MENINGITIS UPON DEMENTIA PRAECOX" *

By E S BARR, M D, R GRANT BARRY, M D,
PHILADELPHIA PA

LAST June, in Atlantic City, at the meeting of the American Psychiatric Association, I read a paper entitled, "Aseptic Meningitis in the Treatment of Dementia Praecox" (7) In that paper was embodied the report of the clinical results obtained, the technique employed, and laboratory findings on the spinal fluid, in forty-nine cases of dementia praecox which were treated in the Philadelphia Hospital for Mental Diseases by the induction of an aseptic meningitis The aseptic meningitis was produced by the introduction of sterile inactivated normal horse serum into the spinal canal after the removal of spinal fluid

Although all the cases reported in that paper were treated in the Philadelphia Hospital for Mental Diseases under the immediate supervision of Dr R Grant Barry, Associate Physician, and the laboratory work was done by Mr David Matzke, Dr Robert S Carroll, of Asheville, N C, was given preponderant credit for the work done because he originated the treatment and first reported it in an article entitled, "Aseptic Meningitis in Combating the Dementia Praecox Problem," which was published in the New York Medical Journal and Medical Record in the issue of October 3, 1923

The paper read in Atlantic City attracted a great deal of attention and quite an extensive correspondence was entered into with hospital men and others throughout the country regarding the "treatment," so called We do not know of any further work having been published on the subject, though the treatment has been tried out in a number of hospitals We are especially glad to have the opportunity of bringing to the attention of the profession at this time a report of the present status of the cases reported a year ago, of the results obtained in other cases treated since that time, and to evaluate the work after the lapse of considerable time since it was first undertaken

The rationale of the treatment is based upon the observation that dementia praecox cases frequently register mental improvement during infectious processes and especially those which are associated with systemic leucocytosis The leucocytosis was assumed to represent "fresh regenerative impulse" (2) The production of systemic leucocytosis was abandoned after a time (1), but Dr Carroll struck upon the idea of producing a meningeal leucocytosis on the theory that the scavenger action of these cells would rid the central nervous system of toxins which were deleterious to its proper functioning

In the first small series of cases treated and reported (1), such striking beneficial results were obtained that after reviewing the literature (3) (4) (5) (6) on which the theory of the treatment was based, we decided to try it on a series of cases at the Philadelphia Hospital for Mental Diseases The first sixteen patients from whose relatives permission was obtained to employ the treatment were a very sorry lot, most of them being cases of long standing and belonging to so-called "deteriorated" classes of unquestioned dementia praecox cases Even so, in that group, twelve patients showed improvement and one young man, who had sunk to a merely vegetative existence, enjoyed a complete remission, gaining insight, and was sent out of the hospital in the care of his delighted and grateful parents This boy relapsed three months later His home surroundings were not good and the family did not carry out our suggestion that he be put to work He was kept closely confined as the neighborhood was rough, and he was giped, when he appeared on the street, with having been in a "nut house," etc After his return to the hospital, he was given five more treatments with improvement, but no remission, and is now a very great deal better than he was before his first treatments He is now cleanly, co-operative, and industrious, went home over Easter and got along very well

Of the forty-nine cases reported last June, we had this to say "There was no improvement, or only temporary improvement, in fourteen cases, six cases have enjoyed remission, one of which relapsed, but responded again to treatment, twenty-eight cases have registered continued improvement or such marked improvement that it should be mentioned, six of them relapsing in from two to four weeks Allowing for relapses sixty-six per cent of cases treated have received benefit which is still lasting after from two to twelve months" The last paragraph is quoted from our paper of a year ago Let us see what is the present status of those cases

* Read at the Annual Meeting of the Medical Society of the State of New York, Syracuse May 13 1925

insufficiency it is likely that the relief of the obstruction will allow the function to return to normal, or almost to normal. If there is arterial hypertension in the presence of a chronic urinary obstruction, there is a good chance that the pressure will be markedly diminished after the relief of the obstruction. In certain cases, unfortunately, the hypertension persists, but in many others the blood pressure falls to a normal figure after operation.

Diverticula and vesical calculi constitute serious complications of urinary obstruction. This is principally due to the fact that when they are present, infection is more apt to occur and is resistant to all forms of local treatment. Stones in the bladder can be removed at the time of operation, and if the obstruction is also completely eradicated, the stones are very unlikely to recur. Small diverticula may give no trouble after the removal of the obstruction, but if they do they must be removed by a second operation. The operation for the removal of diverticula is much more serious than that for the removal of enlarged prostate. In certain cases where the patient is in very good condition, it may be advisable to remove the prostatic obstruction and the diverticula at the same operation.

The cause of the prostatic obstruction is usually benign prostatic hypertrophy, sometimes called "adenoma of the prostate," but it may also be carcinoma of the prostate or contracture of the vesical orifice. Carcinoma of the prostate, however, unless it occurs in conjunction with benign hypertrophy, is not apt to cause urinary obstruction until it is far advanced. It is for this reason that rectal examinations should be made in all male patients over fifty, even if there are no urinary symptoms. Carcinoma can usually be detected on rectal examination, since it nearly always causes the prostate to be extremely hard and irregular, although not necessarily enlarged. In early cases in which the carcinoma is small, it may be removed radically along with the rest of the prostate and seminal vesicles, with excellent prospects of cure. In more advanced cases, implantation of radium, while it may not effect a cure, will usually diminish the local growth to such an extent that urinary obstruction will not occur and the patient's life will be made comfortable. Where urinary obstruction is already present, it may be necessary to operate, removing the central portion of the prostate merely for the purpose of relieving the urinary obstruction. Radium may be implanted at the same time. The results of this operation are surprisingly good, the reason being that carcinoma of the prostate is such a slow-growing tumor that healing of the wound occurs just as rapidly and favorably as in benign cases and the urinary function is restored to normal. The patient is thus saved the great discomfort which accompanies urinary obstruction and the danger of death from uremia,

although we may be unable to prevent an ultimate fatal ending due to metastasis.

Contracture of the vesical orifice is apt to occur at an earlier age than either benign hypertrophy or carcinoma of the prostate. It is usually seen in those with a history of long-standing chronic infection of the urethra and prostate. Its effects on the kidney and bladder are the same as those of other prostatic obstructions and it is therefore just as necessary that this type of obstruction be relieved. In these cases, of course, there is no enlargement of the prostate to be felt by rectum and the special examinations described above are necessary, if one is to make the proper diagnosis. The obstruction can usually be removed by the punch operation, using, preferably, a cautery apparatus. This is done through the urethra and requires no cutting operation. The prognosis in these cases is excellent, providing the obstruction has not existed so long that serious infectious complications are present.

In view of the above facts, it is felt that prostatic obstruction, provided it is not due to carcinoma, is a much less serious disease than is commonly believed, since such good results are to be expected from operations which are practically devoid of danger. It is indeed the pessimistic view of surgical treatment, with its resultant delays, which allow serious complications to result from prostatic obstruction, thereby endangering the patient's life and diminishing the chance of cure by operation. All of these considerations apply with double force when the obstruction becomes so pronounced that complete retention occurs and it is necessary for the patient to be catheterized. As soon as catheterization has begun, infection of the bladder is practically inevitable and this often brings on cystitis and pyelonephritis, which result in serious permanent damage to the kidney and also frequently in the most distressing pain and discomfort to the patient. The dangers of a catheter life are much greater than those of an operation for prostatectomy.

The statements made above are designed to show that it is not necessary to be a specialist in order to make a diagnosis of prostatic obstruction. On the contrary, one can, by the very simple measures described, not only make the diagnosis of prostatic obstruction, but form a very good estimate as to the cause and degree of the obstruction. Since prostatic obstructions are so common in elderly men and since the consequences are so serious, it is certain that a knowledge of this condition is necessary to every one who practices medicine, just as much as the knowledge of heart disease, pneumonia or whooping cough.

puncture was made and 25 c.c. spinal fluid withdrawn. Twenty c.c. of normal horse serum, free from any preservatives, is allowed to flow into the spinal canal by gravity. The patient is now returned to his bed and foot of the bed elevated. T P R are taken every four hours until return to normal. Ordinarily, the temperature rises in the first four to eight hours to 103 deg and gradually returns to normal in four days. If the temperature persists for a longer time, as it does sometimes, no further treatment is undertaken until it returns to normal, both morning and evening.

Sometimes, especially in the early cases treated, we had symptoms of brain edema. These yielded readily to the hypodermic injection of adrenalino and lately we have made the injection of 10 m. of a 1:10,000 solution of adrenaline every four hours a routine procedure until the peak of the temperature has passed and have, for the most part, eliminated these unfavorable reactions. Sometimes there is evidence of anaphylactic reaction, as skin eruption, etc., for which, in addition to adrenalino, the system is thoroughly alkalinized by the administration of sodium bicarbonate by mouth.

During the period of temperature reaction and for several days after, the patient complains of severe headache, especially sub-occipital, and frequently of backache. In some cases, herpes labialis has been noted, and sometimes transient neurological signs, as ocular palsies with complaint of diplopia, etc. Except in the one case before mentioned, these signs have disappeared after a few days and further treatment has never been undertaken as long as they persisted.

As to what happens sub-durally, we reported exhaustively last June the spinal fluid findings in the cases treated and showed color charts of the cells. Briefly summarized, they are: A marked pleocytosis reaching its maximum of from 200 to 300 cells per c.u.m.m. about a week after the third injection. "The polymorphonuclear elements occur in only a very negligible percent. Neutrophilic and basophilic granules occur in their cytoplasm. The cells of the lymphocytic series characterize the bulk of the elements present." There are a number of eosinophiles usually seen after the third injection. There is also observed a type of cell undiagnosed, "a cell which has entirely lost its cytoplasm and whose large round nucleus contains many vacuoles. These nuclei do not stain the blue of the other mono-nuclear elements, but appear a distinct purple in contrast, and as it is impossible to differentiate them from the lymphocyte, mono-nuclear leukocyte, endothelial cell or the nucleus of some other mono-nuclear body cell, it was decided to call them for the present, "undiagnosed" (7). As to the significance of these "un-

diagnosed" cells and the eosinophils which we understand are found in the spinal fluid under no other condition, we are still in the dark.

We have had only one death during the course of the treatments. It is doubtful if this death could have been caused by the aseptic meningitis produced, as the patient had other physical disease as before mentioned. Grossly, the brain showed "edema, thickened piaarachnoid, thick dura. Histologically acute meningitis, the piaarachnoid throughout showed definite infiltration with cells that are mainly polynuclears, especially pronounced about the vessels and present over cortex and base, the vessels, especially the basilar, show little or no sclerosis, the cortex, aside from the very slight glial nuclei increase and pallor of ganglion cells, shows no changes, the spinal cord, aside from meningeal changes, shows no abnormalities."

We are convinced that the production of aseptic meningitis in dementia praecox cases by the introduction of sterile inactivated normal horse serum into the spinal canal, brings about mental improvement in a large percentage of cases. This mental improvement varies from remission of the usual manifestations of dementia praecox, accompanied by insight, to merely better habits being established in deteriorated cases. In some private cases reported by Dr. Carroll, and in two which I treated myself, almost miraculous temporary remissions were manifested. However, both of the latter cases relapsed after a few weeks.

We do not feel that either the meningeal and other physical reactions stirred up by the introduction of sterile normal horse serum into the spinal canal, or the mental improvement which follows this procedure, are due to any specific virtue which resides in the horse serum itself. We rather feel that the mental improvement is due, possibly, to an increased circulation to the central nervous system, perhaps aided in some way by the throwing out of white cells. But we do feel that the demonstration of the fact that mental improvement, even temporary, can be brought about in this way in a large percentage of dementia praecox cases, some even of long standing, is a contribution to science. Some principle is involved here which, if possible to pursue further, may throw much light on the causes of dementia praecox. We intend to follow the clue and continue our research along this line. Even if we demonstrate its futility eventually, we shall have made some contribution to psychiatry by covering ground which other investigators may then pass over.

Briefly summarized, our conclusions are as follows:

1. The introduction of sterile, inactivated, normal horse serum, by a series of treatments, into the spinal canal of cases of dementia praecox produces

KEY TO ABOVE TABLE

Crosses indicate status of case in June, 1924

Stars indicate status of case at present.

Number of each indicates degree of improvement

(1) Died of pulmonary tuberculosis, 3-7-24

(2) Died of pneumonia, 3-3-25

(3) Only one treatment because of very severe reaction

(4) Two more treatments after series

(5) Died of pulmonary tuberculosis, August 13, 1924

(6) Only one treatment because of poor reaction

From these figures, it is apparent that 46 per cent of 48 cases of dementia praecox treated by the introduction of normal horse serum into the spinal canal, registered improvement ranging from merely better institutional adjustment to apparent remission and lasting, in some cases, nearly two years. Many other cases showed improvement for periods varying from two weeks to a number of months. It may be that, eventually, all who showed improvement will return to before treatment states, or even below. Also, we must not be too quick to decide that the improvement still apparent may all be credited to any degree of specificity in the induction of aseptic meningitis. More will be said of that later.

We have been the least but skeptical of the therapeutic wisdom of employing such drastic treatment unless the benefit received were quite marked. Some time ago the question was laid before the medical staff of the hospital, and, because they felt it had too much therapeutic value

to be abandoned, we embarked upon another era of the treatment and have thus far completed sixteen cases with the following results

Case	Age	Years in Hosp	No Improvement	Improved	Worse
49	50	32		X	
50	38	11	X		
51	24	3			X

64	50	2			X (3)

16 5 9 2
(1) Only two injections—peculiar reaction. Now working outside hospital.

(2) Only three injections—unfavorable. Neurological residue (spastic gait)

(3) Die during course of treatments

In this last group of cases patients were included who had been in the hospital for many years, one for thirty-two years, another twenty-two, another nineteen. The average hospital residence for the group was nine years. Even though we might be ever so critical of the treatment, we must, in fairness, admit that such a group could promise little hope of betterment. Even so, nine of the fifteen cases showed improvement varying from better institutional adjustment (less untidy, etc.) to a return to self-supporting life outside the hospital.

Of the two cases charted as "worse," one had an unfavorable reaction after two injections and the treatment was discontinued. He is better mentally, but is classed as worse because of the residuum of a spastic gait, the only persistent unfavorable neurological aftermath in all the cases treated. The other man placed in the "worse" column died. He was a negro, fifty years old, with arterio sclerosis, one atrophic kidney, persistent thymus, and myocarditis—an unsuitable case for any drastic therapy. This was the only death which we have laid directly to the treatments, though we did feel one case of pulmonary tuberculosis was possibly lighted up by treatment.

A few words as to technique. Two nights preceding the treatment, the patient is given two grains of calomel in fractional doses and the following morning a saline. In the afternoon of the day preceding the treatment, the patient is put to bed and placed on liquid diet. These precautions are taken as vomiting was very common at first and especially as green vomitus was frequently seen.

For the administration of the serum, a lumbar

observations are of common occurrence, the subject is nevertheless in need of further study

In the medical management of these local bacterial invasions of the colon wall, the need of a real antiseptic, presenting an ideal combination of high tissue penetrability with low toxicity, has long been felt. The writer is experimenting with some of the aniline dyes and presents a preliminary report herewith, and also in another paper (1)

CASE HISTORIES

CASE 1 (No 5799) Male, 42 years, married. Patient is overworked and has had no proper relaxation for 15 years

Complaint Crises of fatigue and depression associated recently with diarrhoea. Has been subject to attacks of diarrhoea with sweats, chills and fever and rapid pulse and poor sleep. The stools have contained mucus but no evident blood.

Physical Examination Examination showed everything apparently normal except for infected tonsils and three devitalized teeth, one abscessed tooth and three in which the pericementum showed absorption. Frequent examination of the feces showed no mucus, pus or blood, but cultures showed a predominance of *Bacillus coli communior*, a few colonies of *Bacillus lactis aerogenes*, and a few streptococci. Gram-stained smears showed a predominating Gram negative flora. The Gram positive were single cocci, some as diplococci. *Bacillus acidophilus* was scant, perhaps about 5 per cent. A vaccine was made from colon bacilli obtained from these cultures.

Radiographic Studies These studies were confined to the region of the colon. The observations were marked right-sided pericolic membranitis, with what was probably a partially obstructive imbrication involving the transverse colon. The ascending colon was absolutely unobstructed and considerably relaxed. The descending colon showed relaxation also.

The blood examination was interesting and instructive. Red blood cell count was 4,430,000 with 60 per cent of hemoglobin, white cell count 8,450 with 33 per cent of polymorphonuclear cells, 66 per cent of lymphocytes and 1 per cent eosinophiles, showing the common inversion of lymphocytes and polynuclear cells, recently discussed by Draper and Johnson (2). The urine was normal and the blood Wassermann was negative. The blood urea and non-protein nitrogen were high, 33 mg and 32 mg per 100 cc, respectively. (These were taken 6 months after treatment was begun.)

The treatment consisted in detoxicating the patient by the removal of infected tonsils and dental infection and placing the patient on a low protein diet. The patient was also given cultures of acidophilus and colon irrigations with washed Krameria and later with acriviolet solutions.

Hydrotherapy, iron citrate given hypodermically and colon vaccines in minute doses every 4 days were prescribed.

The improvement during 4 months of medical treatment was shown by regular and normal bowel movements, with improved sleep and heart's action. The hemoglobin increased slightly and the leucocyte count rose from 8,450 to 11,220 with an increase in polynuclear cells from 33 to 75 per cent.

Shortly after this examination (December, 1924), the patient had an attack resembling influenza with a temperature of 105°. This was during a mild epidemic of influenza. Nasopharyngeal discharge showed many streptococci. These streptococci then appeared in the feces in large numbers. Diarrhoea returned. Frequent nasal applications of acriviolet dye were given together with vaccines of colon organisms alternating with a vaccine made from streptococci recovered from the feces.

In a month's time, radiographs of the colon were taken again (January, 1925), and the report follows:

"In comparing the barium enema plate with the one taken in August, 1924, it is evident that there has been pronounced improvement in the condition of the entire colon with particular reference to the ascending portion. The imbrication which was so marked in the previous examination seems to be greatly relaxed and the contraction of the transverse colon much less noticeable. The ascending colon is well filled and presents frequent and nearly regular haustral markings. There has been no leakage into the terminal ileum. The marked improvement in the right side indicates the value of medical measures in handling these cases."

Although the physical condition of the patient was very markedly improved by the detoxication and immunization, his physical endurance was very poor. For this reason prolonged rest in Europe was advised and accepted. He is still continuing vaccine therapy and the use of the aniline dyes.

Points of interest in this case of toxic neurasthenia

- 1 Effect of prolonged overwork and strain on an already existing intestinal (colon) infection
- 2 Improvement after (a) detoxication and (b) immunization by carefully selected vaccines
- 3 Sudden appearance of influenza and streptococci in the feces
- 4 Value of aniline dyes in colon infections
- 5 Need of prolonged rest following these procedures

CASE 2 (No 4444) Male, 30 years, single

Complaint Lowered efficiency and vitality, secondary tendency to constipation and gas. At the age of 15 years, the patient remembers stomach upsets. He first came under observation in January, 1922, with malaise, rapid pulse, flatus

CHRONIC INTESTINAL INFECTIONS NON-ULCERATIVE TYPES *†

By G REESE SATTERLEE, M D

NEW YORK CITY

AS the title of this paper indicates, the ordinary types of ulcerative colitis have been excluded as far as possible by clinical and pathological methods. There remain, however, a very large number of patients in whom there is roentgenological evidence of chronic colitis together with a suggestive clinical history of either diarrhoea or constipation or both. On the other hand, there are patients in whom the historical evidence is negligible, and in such cases, the physical and roentgenological findings must be relied upon almost exclusively.

The source of the majority of these colon infections is undoubtedly to be found in the oral cavity, but it is by no means certain that other foci do not also play an important part by spreading infection to the intestine by the blood stream and lymphatics. In some cases we know that proctitis and infected hemorrhoidal crypts result in an ascending infection involving the colon. Chronic constipation with its resultant irritation of the walls of the colon by hardened scybala is a common predisposing cause. The inverse may also be true, namely, that constipation can follow a generalized infection of the colon mucosa. Such constipation is of the protective type.

From the viewpoint of a specific bacterial etiology, the cases may be classified into three general groups (1) colon disorders sequential to contagious diseases, such as influenza, scarlet fever, and other allied infections of the streptococcic type, (2) local colon infections caused chiefly and primarily by various forms of strep-

tococcus and colon bacillus, (3) somewhat obscure infections caused probably by anaerobic organisms. This last group will not be discussed in this paper. Typhoid fever has not been included as a separate etiological entity because it is accepted that the typical lesions produced by *Bacillus typhosus* are ulcerations of the intestinal mucosa. Typhoid fever may become, however, an important predisposing factor in the later development of chronic colon disease. The ordinary pyogenic organisms that are found in the stools of chronic intestinal invalids should be regarded as either accidental or as evidence of ulcerative processes.

This paper is chiefly concerned with the consideration of colon disorders produced by two types of aerobic organisms—the colon bacillus and the streptococcus. Since there are numerous varieties of these organisms, it has been found most practical to culture and select them for specificity according to the method of Holman. Many of these organisms are of no pathological significance and may be present in the feces of normal individuals, just as the pneumococcus may be present in the sputum of an individual not suffering from pneumonia.

It is important to bear in mind that the streptococcus may be and frequently is the first offender in these colon infections and that the colon bacillus often plays a rôle of secondary etiological importance. In this connection it has been interesting to note the frequent occurrences of large numbers of streptococci in the stools of patients convalescing from an attack of influenza or an attack of streptococcic nasopharyngeal infection. One illustration of the above conditions has been cited in the case histories to follow. While these

† Aided by a grant from the Andrew Todd McClintock Memorial Foundation for the Study of Gastrointestinal Diseases.

observations are of common occurrence, the subject is nevertheless in need of further study

In the medical management of these local bacterial invasions of the colon wall, the need of a real antiseptic, presenting an ideal combination of high tissue penetrability with low toxicity, has long been felt. The writer is experimenting with some of the aniline dyes and presents a preliminary report herewith, and also in another paper (1)

CASE HISTORIES

CASE 1 (No 5799) Male, 42 years, married. Patient is overworked and has had no proper relaxation for 15 years

Complaint Crises of fatigue and depression associated recently with diarrhoea. Has been subject to attacks of diarrhoea with sweats, chills and fever and rapid pulse and poor sleep. The stools have contained mucus but no evident blood.

Physical Examination Examination showed everything apparently normal except for infected tonsils and three devitalized teeth, one abscessed tooth and three in which the pericementum showed absorption. Frequent examination of the feces showed no mucus, pus or blood, but cultures showed a predominance of *Bacillus coli communior*, a few colonies of *Bacillus lactis aerogenes*, and a few streptococci. Gram-stained smears showed a predominating Gram negative flora. The Gram positive were single cocci, some as diplococci. *Bacillus acidophilus* was scant, perhaps about 5 per cent. A vaccine was made from colon bacilli obtained from these cultures.

Radiographic Studies These studies were confined to the region of the colon. The observations were marked right-sided pericolic membranitis, with what was probably a partially obstructive imbrication involving the transverse colon. The ascending colon was absolutely unobstructed and considerably relaxed. The descending colon showed relaxation also.

The blood examination was interesting and instructive. Red blood cell count was 4,430,000 with 60 per cent of hemoglobin, white cell count 8,450 with 33 per cent of polymorphonuclear cells, 66 per cent of lymphocytes and 1 per cent eosinophiles, showing the common inversion of lymphocytes and polynuclear cells, recently discussed by Draper and Johnson (2). The urine was normal and the blood Wassermann was negative. The blood urea and non-protein nitrogen were high, 33 mg and 32 mg per 100 c.c., respectively. (These were taken 6 months after treatment was begun.)

The treatment consisted in detoxicating the patient by the removal of infected tonsils and dental infection and placing the patient on a low protein diet. The patient was also given cultures of acidophilus and colon irrigations with washed *Krameria* and later with acriviolet solutions.

Hydrotherapy, iron citrate given hypodermically and colon vaccines in minute doses every 4 days were prescribed.

The improvement during 4 months of medical treatment was shown by regular and normal bowel movements, with improved sleep and heart's action. The hemoglobin increased slightly and the leucocyte count rose from 8,450 to 11,220 with an increase in polynuclear cells from 33 to 75 per cent.

Shortly after this examination (December, 1924), the patient had an attack resembling influenza with a temperature of 105°. This was during a mild epidemic of influenza. Nasopharyngeal discharge showed many streptococci. These streptococci then appeared in the feces in large numbers. Diarrhoea returned. Frequent nasal applications of acriviolet dye were given together with vaccines of colon organisms alternating with a vaccine made from streptococci recovered from the feces.

In a month's time, radiographs of the colon were taken again (January, 1925), and the report follows:

"In comparing the barium enema plate with the one taken in August, 1924, it is evident that there has been pronounced improvement in the condition of the entire colon with particular reference to the ascending portion. The imbrication which was so marked in the previous examination seems to be greatly relaxed and the contraction of the transverse colon much less noticeable. The ascending colon is well filled and presents frequent and nearly regular haustral markings. There has been no leakage into the terminal ileum. The marked improvement in the right side indicates the value of medical measures in handling these cases."

Although the physical condition of the patient was very markedly improved by the detoxication and immunization, his physical endurance was very poor. For this reason prolonged rest in Europe was advised and accepted. He is still continuing vaccine therapy and the use of the aniline dyes.

Points of interest in this case of toxic neurasthenia:

- 1 Effect of prolonged overwork and strain on an already existing intestinal (colon) infection
- 2 Improvement after (a) detoxication and (b) immunization by carefully selected vaccines
- 3 Sudden appearance of influenza and streptococci in the feces
- 4 Value of aniline dyes in colon infections
- 5 Need of prolonged rest following these procedures

CASE 2 (No 4444) Male, 30 years, single.

Complaint Lowered efficiency and vitality, secondary tendency to constipation and gas. At the age of 15 years, the patient remembers stomach upsets. He first came under observation in January, 1922, with malaise, rapid pulse flatu-

lence, slight constipation and many varied sensory symptoms, nervousness, aches and pains, phobias and insomnia

Physical Examination Examination showed rapid pulse, blood pressure of 110/80, dry skin, pustular acne, infected tonsils, hemorrhoids with tight anal sphincter and one infected tooth. Gastrointestinal examination showed a large redundant colon with low grade inflammatory changes, particularly on the right side, where there was an inseparable coil at the hepatic flexure. There was a mild incompetence of the ileocecal valve. There was total colon stasis. Blood Wassermann was negative. Hemorrhoidectomy was performed on August 1, 1924. The following October, the patient's blood pressure was 118/90 and pulse 98. The stool was putrefactive in character and contained a very great excess of *Trichomonas intestinalis*. He was placed on antiputrefactive diet and given large doses of thymol on the supposition that the trichomonas in such large quantities in the stool might be pathological. After a week of thymol, trichomonas were still numerous. Autogenous colon vaccines were then prepared and the colon irrigated with acriviolet solution, 1 35,000, which was retained for 20 minutes after the method of Churchman (3). Local and general reactions followed vaccine with slight temporary cervical adenitis. After a month of this treatment, trichomonas disappeared and the patient was brighter and stronger, but had occasional intestinal flareups with constipation. The vaccines gave more severe reactions and the dosage was diminished. Basal metabolism was minus 10. Examination of the feces showed acidophilus to be 20 per cent of the entire flora. The stools were acid, loose and contained many trichomonas. Vaccines and acriviolet solution treatments of the colon were continued. The stool showed a slightly acid reaction, a moderate number of trichomonas and a few streptococci and colon bacilli. A radiograph of the colon about this time showed a much better tone than 6 months previously, the right-sided angulation was still present, the ascending colon had better appearance and there was less ileocecal leakage.

In spite of increased well being and efficiency, the blood pressure continued to decrease until it registered 90/70, in March, 1925. An infected bicuspid with a granuloma was then extracted. The stools still showed trichomonas in large quantities whenever the acriviolet solution irrigations were discontinued. Fifty c.c. of an acriviolet solution 1 1,000 (0.052) gm were given into the duodenum through a duodenal tube. Seventy-two hours later the dye was recovered in the feces and the trichomonas disappeared. Later the dye in solution was given by mouth successfully.

The stool on May 19, 1925, which was the

largest formed stool in the history of the case, was passed 5 days following the administration of 0.078 gm acriviolet through the duodenum. There was a distinct line of demarkation between the dye and an unstained portion of the stool, showing that it took 5 days to eliminate the dye through the intestine. The culture showed about 50 per cent acidophilus (Acidophilus culture milk had been taken since the administration of the dye). Acidophilus predominated in the unstained portion of the stool. Trichomonas, less than 1 per cent, were present in the unstained portion. The patient's mental efficiency and power of endurance has been greatly benefited by 8 months of treatment.

Points of interest in Case 2

- 1 Excessive mental and nervous depression associated with and apparently dependent upon intestinal toxemia

- 2 Excessive amount of *Trichomonas intestinalis* in feces

- 3 Value of selected autogenous vaccines in immunization

- 4 Beneficial results of aniline dyes

- 5 Radiographic evidence of improvement in colon parallel to that of physical improvement

CASE 3 (No 4192) Female, age 62 years, married

Complaint Chronic intestinal invalid for years. General hypersusceptibility to many food stuffs, drugs and infection. Her susceptibility to infection was not helped by an extensive amount of badly constructed dental repair work, bridges, crowns, caps, pivot teeth, which included, of course, many dead teeth. When first seen in August, 1921, the patient was a profound neurasthenic in bed with loss of appetite, loathing of food, irregular bowels, diarrhoea, constipation and mucus in the stools. She was relieved of a mass of gold plate and many infected teeth which had produced necrosis of both maxillae and chronic maxillary sinusitis.

These operations were followed by marked relief in symptoms. Within 2 months, tonsillectomy and hemorrhoidectomy for infected tonsils and hemorrhoids, were performed. The cervix was slightly infected and curetted. At this time, the patient weighed 119 lbs and was 5½ ft in height. The stools showed undigested food, mucus at times. Cultures were taken from the feces and vaccines obtained from colon organisms (*B. acidilactici*) were given. These were discontinued because of the severe reactions, but given later in small doses with success, February, 1922.

There was marked improvement and the weight reached 130 lbs. The patient was more or less invalided throughout 1922, and the winter of 1923, during which time colon vaccines were regularly given. A most interesting factor in relieving the nervous symptoms was demonstrated through the isolation of two organisms of the colon group, *Bacillus communior* and *Bacillus*

Morgagni, from the stools. Intradermal tests showed marked reactions from both but very severe from *Bacillus Morgagni*. Small doses of vaccine made from the organisms demonstrated conclusively their value, relieving the nervous symptoms and enabling the patient to convalesce. Today, May, 1925, she weighs 137 lbs., as against 119 lbs. four years ago.

Points of interest in the case

- 1 Bacterial origin of the neurasthenia
- 2 Necessity of removal of foci of infection
- 3 Value of immunization by means of carefully selected organisms
- 4 Interrelationship of food and bacterial proteins

5 Value of aniline dyes as bactericides

CASE 4 (No 5084) Female, 36 years of age, single. This case is included because we have a full report of Dr James Ewing's pathological examination of the colon following colectomy.

Complaint Extremely severe attacks of migraine for 6 years. Impossible to move bowels without strong cathartics. One of the colon group of organisms (*Bacillus neapolitanus*) was isolated from the stool and from which a vaccine was made. This vaccine produced such profound reactions that it was discontinued. After the removal of foci in the mouth (infected teeth and tonsils), infected cervix and rectum, abdominal section was performed and a badly diseased and obstructed colon was removed. The result was relief of headaches and marked improvement for 2 years.

Pathological Report "Specimen consists of about 15 inches of colon and 5 inches of ileum. The entire mucosa of the colon is moderately pigmented. There are no definite ulcerations or erosions. Just above the ileocecal valve and again 6 inches above the valve, there are definite hernia pouches $1\frac{1}{2}$ cm deep and 2 cm wide, in which the mucosa is very thin and the muscle atrophic, rugae obliterated. The colon seems to be of about normal dimensions. The ileum shows no gross changes.

On microscopic section the most striking feature is pronounced chronic catarrhal enterocolitis. The mucus cells are enormously increased in number. The lining epithelium of the ileum and of colonic rugae and the glands is markedly hypertrophic. In the colon there is general marked lymphatic infiltration of the mucosa.

Anatomical Diagnosis Chronic catarrhal enterocolitis, diffuse pigmentation, hypertrophy of lining epithelium, multiple herniae of colon mucosa.

The histories of Cases 5 and 6 have been omitted for the sake of brevity. Case 5 was one of long-continued colitis of ascending origin from a proctitis. The nervous symptoms overshadowed the local colon signs, which were therefore overlooked.

Case 6 was one of extreme mental and nervous depression due to focal infection and chronic colitis. The colitis was severe but undiagnosed. Both these cases responded well to detoxication and immunization.

It is most unfortunate that there has been great limitation in the extent of the colon studies made in the type of cases considered in this paper. This has been due to the fact that very little has been known until the last year or so about the pathology of the colon, for as yet there is no recognized standard upon which to base analytical studies. That this is so, is evidenced by the frank acknowledgement by Dr Ewing (4), who has explained our lack of knowledge of the diseased colon by the great scarcity of fresh tissue available to the pathologist in the past.

It will be readily seen therefore that one of the great benefits arising from the intensive study of the subject by Dr Cotton and Dr Draper, in the State Hospital, at Trenton, New Jersey, will be the dissemination of accurate knowledge of the lesions of the colon based upon a careful study of fresh specimens removed at operation.

It has been the author's privilege to study over three hundred of these pathological specimens. These have been removed during the past seven years in the surgical clinic of the New Jersey State Hospital, by the writer's associate, Dr John W Draper, under the supervision of the medical director, Dr Henry A Cotton. He has also derived much information in the private practice of Dr Draper and himself. Such a cooperative effort will undoubtedly lead to a more perfect understanding of this intricate subject.

It is above all necessary for those who make the preoperative observations, roentgenological and otherwise, to be present at the time of operation. For only by a constant process of trial and error can one reach any clear comprehension, preoperatively, of these little-understood colon lesions. These must be seen *in vivo* to be appreciated and understood. In some instances, in our private work, we have found that freeing the constricted bowel by the removal of bands and adhesions has been all that was necessary. In others, the removal of the colon seemed, as stated by Dr Ewing some three years ago, and based upon a study of our material, to be the only procedure indicated to give relief. The original studies by Ewing have been augmented recently by a much more complete series by Dr John W Churchman (5), whose observations were presented in a paper from the Andrew Todd McClintock Memorial for the Study of Gastrointestinal Diseases, and recently read before the Mayo Clinic. This monograph gives a very full, explicit and convincing account of his study of 165 colons from Dr Draper's hospital series. This paper is well illustrated and should be read by all those who are interested in the subject of the relationship of the colon lesions

to nervous and mental disorders. Obviously, it is only through long experience in comparing roentgenological examinations with the surgical observations at operation or the postmortem specimens, that one can become at all proficient in identifying colonic lesions and in reaching a decision with reasonable accuracy regarding their extent and probable cause.

The roentgenological findings, as has often been emphasized in previous communications on the subject of colon lesions, are not necessarily accompanied by intestinal delay. Indeed, the word "stasis" which has crept into colonic literature is exceedingly objectionable. We feel that undue speed and spasm, as indicated in the x-rays, are quite as frequent accompaniments and indicators of serious colon lesions as are delays. One fairly conclusive observation is that the occurrence of the so-called segmental colonic lesions which have been observed and described by many critical students, should be explained frequently by the presence of constricting bands. The colon is resentful of such pressure. It interferes with the rhythm of peristalsis, in the early stages produces spasms and later causes serious destruction of the bowel wall. This leads to leakage, to chronic peritonitis and to absorption of extremely toxic products, many of which are selective to important parts of the nervous system. It is for this reason that we agree with those who advocate section or removal of these bands in childhood.

There is no doubt that they constitute a very real and serious menace to adult life.

SUMMARY OF TREATMENT

- 1 Thorough roentgen ray studies
- 2 Removal of focal infections, particularly of the teeth, tonsils and accessory sinuses
- 3 Removal of toxic products from the colon by irrigation
- 4 Local application of germicides, such as the aniline dyes, to the gastrointestinal mucosa.
- 5 Immunization by natural methods and by autogenous vaccines obtained from feces or by sera
- 6 General hygienic measures, including rest and regulation of diet
- 7 In refractory cases, operation

The author wishes to acknowledge his indebtedness to the Andrew Todd McClintock Memorial Laboratory for the routine laboratory and research work.

HISTORY, PHYSICS, AND BIOLOGICAL EFFECTS OF RADIUM*

By G ALLEN ROBINSON, M.D.,

NEW YORK CITY

Radioactive substances and their radiations are a result of the discovery of the X-ray. In a search for invisible light rays Professor Wilhelm Konrad Roentgen turned on a low pressure discharge tube which was enclosed in stout black paper, and noticed that a fluorescent screen lying on a table some three meters away shone out brightly. If obstacles were interposed he found that they cast shadows on the screen, and, in this way traced back the unknown or "X" rays to their source, which proved to be the region of impact of the cathode particles or negative electrons on the glass walls of the tube. He at once appreciated the significance of his discovery to the medical profession and communicated his results to the Physics-Medical Society of Wurtzberg, Bavaria, in November, 1895.

The impetus of Roentgen's discovery led to a general search for phosphorescing bodies that emit penetrating radiations. Professor Henri

Becquerel examined crystals of the double sulphate of uranium and potassium which he had prepared fifteen years before. He wrapped a photographic plate in two layers of thick black paper so that the plate would not be fogged even if the package were exposed to the direct sunlight for an entire day. On the outside of the paper enclosing the plate was laid a crystal having the form of a thin transparent crust, and the whole was exposed to the sun for several hours. The plate was then developed and on it was found a black silhouette of the phosphorescent crystal. He found that the interposition of a thin sheet of glass between the phosphorescent crystal and the black paper did not change the appearance of the silhouette. This proved that the effect could not be ascribed to a gas given off by the crystal. He also found that metal objects placed between the crystal and the paper cast shadows on the silhouette. He then found that these same effects could be produced through a plate of aluminum and through thin copper foil.

*Read before the American Electrotherapeutic Association, Chicago, Sept. 16, 1925.

The announcement of this new property of matter, radioactivity, was made by Becquerel to the Academy of Science, Paris, February 24, 1896. There are four main properties of radioactive substances¹. First, the effect on a photographic plate, similar to that of light or X-rays, second, phosphorescence or fluorescence is excited in certain substances, third, ionization of gases; and, fourth, the production of heat. One gram of radium gives out 133 calories per hour.

Among Becquerel's students at the University of Paris was Marie Skłodowska, of Poland (afterward Mme Curie). To her was committed the problem of determining what substances were radioactive. With the collaboration of her husband, M. P. Curie, she undertook the problem of isolating these elements. Mme Curie found that certain natural minerals were more radioactive than uranium itself. Thus, some varieties of pitchblende, particularly that from the Joachimsthal mine in Austria, contained 50-80 per cent uranium oxide and were about four times as active as the purer uranium.

Hence, one of two things must be true (1) that radioactive substances had entered into chemical combination and the activity increased, or, (2) some other radioactive substance other than uranium was present. M. and Mme Curie relied on the more plausible hypothesis that a new element existed, and by a systematic chemical analysis two new elements were soon discovered. The first of these was separated with bismuth and was highly radioactive. The name polonium was given to this element by Mme Curie in honor of the country of her birth. It was next observed (1898) that another radioactive substance was separated with barium and to this was given the name radium. A gold-leaf electroscope was employed to measure the ionization produced by the radioactive substance.

Rutherford and Soddy developed the theory that atoms of radioactive substances constantly undergo spontaneous disintegration². The radium atom disintegrates with the expulsion of an alpha particle and the residue of the atom forms an atom of radium emanation or radon. The alpha particle is known to be a doubly charged positive atom of helium with an atomic weight of 4. Radium emanation is a gas and is proportional to the quantity of radium present. The equilibrium amount of radium emanation with one gram of radium is termed a curie and has a volume of 0.6 cubic millimeters. The total radiation of one millicurie of emanation is equivalent to approximately 133 millicurie hours of continuous radiation. Radium emanation undergoes a radioactive change with the loss of an alpha particle and the production of an atom of Radium A, which in turn loses an alpha particle with the production of Radium B. Radon is the name suggested in 1923 by the International Committee on Chemical

Elements to replace the term "Radium Emanation".

Radium B and Radium C are the sources of the therapeutic rays which are the beta and gamma rays. The beta rays or particles are single negative electrons and in their escape from the atoms of Radium B and Radium C produce high frequency electro-magnetic waves, the gamma rays. The gamma rays are analogous to X-ray, ultra-violet and visible light, differing from these, however, in having a shorter wave length.

TABLE I

URANIUM-RADIUM SERIES (3)			
Substance	Atomic Weight	Time to Decay to Half Value	Radiation Emitted
Uranium 1	238	5 billion years	alpha
Uranium X ₁	234	24.6 days	beta and gamma
Uranium X ₂	234	1.15 minutes	beta and gamma
Uranium 2	234	About 1,000,000 yrs.	alpha
Ionium	230	About 100,000 yrs.	alpha
Radium	226	1680 years	alpha
Radium Emanation (Radon)	222	3.85 days	alpha
Radium A	218	3 minutes	alpha
Radium B	214	26.8 minutes	beta and gamma
Radium C (99.97%) (0.03%)	214	19.5 minutes	Alpha beta gamma
Radium C ₂ (0.03%)	210	14 minutes	beta and gamma
Radium C ₁ (99.97%)	214	0.000001 seconds	alpha
Radium D	210	16.5 years	soft beta
Radium E	210	5.0 days	soft beta
Radium F (Polonium)	210	136 days	alpha
Radium G (End Product Lead)	206		No rays Atoms stable

There is a wide difference in the penetration of the alpha, beta and gamma rays. The alpha rays will not penetrate a thin sheet of writing paper and are absorbed by three centimeters of gaseous air. The beta rays are screened off by two millimeters of lead or brass. The gamma rays will penetrate 10 or more centimeters of lead. The beta ray is 100 times more penetrating than the alpha, and the gamma 100 times more penetrating than the beta. As to quantity, the alpha rays compose 90 per cent, the beta 9 per cent and the gamma 1 per cent of the radiations.

The source of radium in this country is from carnotite ore, which is found in Colorado and Utah. The ore contains from 2 per cent to 5 per cent of uranium oxide and yields 3 to 15 milligrams of radium per ton. The Belgian mines in Congo, Africa, yield ores considerably richer than the American supply.

It is interesting to note briefly the process of extraction of radium from the ores. To 1,000 lbs of ground ore is added 500 lbs of concentrated hydrochloric acid and allowed to cook for one hour. The liquid contains radium barium chloride and vanadium uranium chloride. The by-product vanadium is used in hardening steel. The radium and vanadium are separated by the addition of sodium sulphate which precipitates the radium in the form of radium barium sulphate and is converted into radium barium car-

bonate by the addition of sodium carbonate. The final separation may be affected by fractional crystallization. The radium barium carbonate is converted into radium chloride and barium chloride by the addition of hydrochloric acid, radium chloride being less soluble than barium chloride.

TABLE II

THE AMOUNTS OF RADIUM THAT ARE CONTAINED IN CERTAIN PURE RADIUM SALTS

Name of Salt	Chemical Formula	Weight of Salt per 100 mg of Radium	Weight of Radium in 100 mg of Salt
		mg	mg
Radium Bromide, Crystallized	$\text{RaBr}_2 \cdot 2 \text{H}_2\text{O}$	187	53.6
Radium Bromide, Anhydrous	RaBr_2	171	58.6
Radium Chloride, Crystallized	$\text{RaCl}_2 \cdot 2 \text{H}_2\text{O}$	147	67.9
Radium Chloride, Anhydrous	RaCl_2	131	76.1
Radium Sulphate	RaSO_4	142	70.2
Radium Carbonate	RaCO_3	126	79.0

The International Radium Standard consists of an hermetically sealed thin glass tube containing 21.99 milligrams of pure radium chloride, which was prepared in 1912 by Mme Curie, and approved by the Congress of Radiology and Electricity. It is preserved in the Bureau International des Poids et Mesures at Sevres, near Paris. A second standard which has been most carefully compared with this is kept at Vienna. The United States Radium Standard contains 15.44 milligrams of radium and has been compared with the International Standard, and also with the standard at Vienna.⁴

Biological Effects of Radium

The effects produced by the action of the radium rays on the skin were first recorded by Walkoff in 1900, and shortly afterward by Giesel.⁵ However, radium treatment did not receive its initial impetus until after the famous "Becquerel burn" in 1901. Becquerel placed a tube of very active radium in the pocket of his waistcoat where it remained for several hours. Two weeks later a severe inflammation of the skin appeared, which was attributed to the action of the radium. Curie then made an experiment on himself, and loaned a specimen to Dabolo of the Saint Louis Hospital, Paris, for medical purposes. Williams of Boston, and Abbe of New York, were the first American physicians to use radium with any degree of success. Abbe's first article "Radium and Radio-activity" was published in 1904.

The difficulties in radium therapy at first were the limited supply of radium available for medical purposes and the lack of a suitable accurate method for standardizing radium preparations.

Radium emanation tubes or applicators in the form of a source of therapeutics have been used first at the Radium Institute in Paris. The use of radium in the form of plaques, employed. The

technique used depends upon the skill and experience of the operator. Different methods will often produce the same end-result. Progress in radium therapy depends upon the development of our knowledge of the physics and chemistry of radium and a better understanding of the life history and structure of neoplasms.

A radium plaque 2 centimeters square and containing 10 milligrams of radium is commonly used. Both beta and gamma rays are available in an unscreened plaque, the proportion being about 9 to 1. By covering the plaque with a lead screen 2 millimeters thick the beta rays are screened off. In dermatology, in which radiation within 1 to 5 millimeters in depth is required, the plaque is invaluable. The application of the 10 milligram half strength radium plaque to the skin will produce an erythema in ten minutes, and an erythema and temporary epilation in fifteen minutes. A one-half hour exposure will produce a heavy reaction with exudation and result in a permanent epilation.

Radium needles contain usually 5 to 10 milligrams of radium each. A convenient type of needle is 20 millimeters in length, has an external diameter of 1.25 millimeters and a wall thickness of 0.2 millimeters platinum. The advantages of radium needles are that they may be inserted directly into tumor tissue giving off radiation in all directions and not affecting the normal tissue to any great degree. The 0.2 millimeters of platinum will reduce the beta radiation to approximately 1 per cent, and, therefore, the radiation is almost entirely that of the gamma ray.

Radium needles are inserted into tumor tissue approximately 1 centimeter apart and allowed to remain from two to eight hours, depending upon the radiosensitivity of the tissue. For insertion in body cavities radium needles may be grouped in brass or platinum capsules 3 centimeters long and having an external diameter of 0.5 centimeters.

Radon in glass ampoules are used for intratumoral radiation and consist usually of 0.5 to 1 millicurie each, and are about 3 millimeters long and 0.3 millimeters in diameter. The ampoules may be sterilized by boiling and inserted into a sharp end of a sterile needle with a plunger at the other end. The needle should be withdrawn a few millimeters just before the plunger ejects the ampoule, so that the radon may rest in the cavity thus formed. Intense beta radiation plus gamma radiation is obtained from radon implants, and a small zone of liquefaction necrosis is produced around each implant. In resistant localized neoplasms where caustic effects are indicated radon is invaluable.

Recently radon implants have been screened with 0.2 millimeters of brass or platinum. This procedure reduces the intensity of the inflammatory reaction and the area of complete necrosis. The effect of the screened radon is mainly that of

the gamma ray and similar to that of the screened radium element. Deep seated neoplasms are usually inaccessible and too extensive for the application of interstitial irradiation. External radium packs at a distance of 3, 5 or 10 centimeters are used, depending upon the depth of the tumor. Large amounts of radium are necessary for this procedure thus limiting its use. Combined irradiation with radium packs and deep X-ray retards the activity of the growth and prolongs the life of the patient.

Bergonie and Tribondeau have stated that tumors composed of rapidly multiplying cells, especially those of the lymphoid group, are highly susceptible to irradiation and in such ratio as to the above characters are developed. Lymphosarcoma, tuberculous adenitis, lymphatic leukemia, angiomas, embryonal carcinoma of ovary or testis and basalcell epidermoid carcinoma are grouped as radiosensitive. Osteosarcoma, squamouscell epidermoid carcinoma and fibrocarcinoma are relatively radio-resistant.

Within two or three days following a radium application to an erythema dose there is noticed on microscopic examination a swelling of the cell bodies and a hyperchromatism of the nuclei. During the second and third weeks the cytoplasm undergoes liquefaction, the cell membrane ruptures and the nuclei become broken up. An inflammatory reaction is present with a serous exudation and infiltration of lymphocytes. During the fourth week there is a formation of new capillaries and granulation tissue. The end-result of the process is the formation of dense fibrous tissue which replaces or encapsulates tumor cells and acts as a protective barrier to their dissemination.

THE HERALD OF THE MEN OF DEATH *

By THOMAS F REILLY, M D,
NEW YORK CITY

IN order that we may make clear the title of the paper, it is necessary to state that a herald is one who goes before the king to announce his coming, and as it were to introduce him and to make straight his path. Osler has nominated Pneumonia as the "Captain of the men of Death," because Pneumonia is the commonest disease present as a fatal termination in illnesses of all kinds. This Pneumonia is by no means always Lobar Pneumonia, but is most frequently, at least at the present time, a typical Influenza Pneumonia, which in the last analysis is a catarrhal Pneumonia, so that in a very large proportion of cases Influenza is not only "Herald," but "Captain" of the men of Death.

On another occasion, we have pointed out the relation that exists between cardiac decompensation and attacks of Influenza. Formerly, pathologists considered the so-called chronic diseases as progressively spreading processes, much as a cancer spreads, but our present concept is that chronic bacterial disease only spreads by a series of acute attacks. We have pointed out that the most common attacking agent after the field of infection has been prepared by Rheumatism, Syphilis or Arterio-sclerosis, is the Influenza organism, or an infection of some kind associated with the symptoms and signs commonly attributed to Influenza.

The great cardio vascular renal group of diseases, comprising as it does sixty per cent of all

chronic disease in adults, is so commonly stirred up by this influenzal agent that one might well consider influenza as the chief terminal infection in this group. This concept eliminates barrels of digitalis, so commonly administered at present in the treatment of what is in reality an acute endocarditis, the belief being general that decompensation is somehow or other the cause of the fever, when as a matter of fact the decompensation is mostly the result rather than the cause.

A similar condition of the mucous membranes is to be noted at the onset of most hemiplegias. In the final analysis, the stroke is usually a vascular accident, and is analogous to an attack of cardiac decompensation. In most hemiplegias, if one will look at the mouth and throat of the patient, an exact replica of the mouth of a person suffering from broken cardiac decompensation with influenza is revealed. This patient, just as the cardiac, will deny that he is or has recently been the victim of a head cold, until one points out the manifestations in the mucous membrane, and thus proves the picture to his friends.

The great question will always be raised as to why the patient, who felt so well when he went to bed last night, wakes up this morning with a hemiplegia. His heart, arteries or kidneys may have been damaged for years, but they were no worse last night than they were months ago, but why did the catastrophe happen last night? The answer, we believe, is that within a day or so he contracted the influenzal infection, which just ripened or exploded or invaded the blood stream.

* Read at the Twenty seventh Annual Meeting of the American Therapeutic Society, Atlantic City, May 22, 1925.

last night and alighted on an already damaged vessel and produced the lesion either of thrombosis or of hemorrhage. As to which of the two latter pathological conditions occurs depends on his particular family history, whether it was that his ancestors readily developed a thrombosis, or hemorrhage, rarely embolism.

From the heart and vascular system it is only a step to explain a similar train of infection in damaged kidneys. Here again the lesion is often a vascular one. In a series of cases of decompensating kidneys we have been struck by the usual story of the patient that he had a head cold for the week or more preceding the onset of kidney symptoms. The same is true in at least some cases of eclampsia. The onset of diabetic coma has in our experience been often ushered in with the evidence of influenza in the mucous membranes. The universal accompaniment of influenza at the commencement of encephalitis makes it difficult for one to believe that the encephalitis is not really a form of influenza, or else that influenza in some way paves or heralds its appearance and prepares the way for its onset. It would appear that most of us are hosts of the influenza organism, which for long periods remains dormant, and that at certain times, and under certain conditions, the organisms become active. Probably nervous shock, as well as a physical shock, may be the exciting agent, but this leads us to theorizing, and inasmuch as our contribution is merely to call attention to the relation of lethal disease with the presence of the signs of so-called influenza in the mucous membrane, signs that are exactly the same that we meet with in unquestioned influenza, and which are present at the onset of most of the infectious disease processes that occur in the human body, we do not feel warranted in being positive in this matter as to the how of activation.

The frequency with which sore throat is followed by appendicitis within a few days, long ago led Rosenow to predicate that the germs were dormant in the teeth or tonsils, and he has successfully proved his contention that there is a chemotactic attraction between the germs at times present in the throat and inflammatory attacks of the appendix, gall bladder, and the upper portion of the gastric tract. His attempt to settle on the particular germ is not so clear, any more than that we do not know the germ of influenza. Or witness the symptoms preceding the onset of the gastric or duodenal ulcer syndrome, or the multitude of gastric complaints which simulate the ulcer syndrome, but of the exact diagnosis of which we cannot be quite sure, in some respects the opinion favoring gall bladder disease, in others appendicitis, and yet in others simulating gastric ulcer. In most of these patients a close inspection of the mouth will, a few days before, or in the early part of the affection, reveal unmistakable signs of influenza. The layman is

accustomed to say, 'I think I have taken a cold in my stomach.' Everyone will have noted the great frequency of digestive complaints in those who have had a mild attack of influenza. This association of influenzal signs of the mucous membrane, to be described, preceding the recurrent attack of stomach distress, and which signs persist to some degree as long as the attack itself, adds much interest to an otherwise dull case.

The belief that appendicitis, so common now as compared to the past, is not due to better diagnosis, as many assert, but that it really appeared in a widespread form in this country following the influenza epidemic of 1888-1889, is widely held. Certainly now it is a widespread disease, and the increase must be evident to everyone. Each of the great influenza epidemics seem to be followed by the relighting of a certain special type of disease, the present one by the incidence of encephalitis, by high blood pressure, by hyperthyroidism, and possibly by diabetes. I am sure everyone, during the past six years, has noted the great increase of diabetes. It is not due to better diagnosis, as we were quite as careful in making sugar examinations twenty-five years ago as today. Certainly the same routine is in use that was prevalent when I was a house physician more than a quarter of a century ago, when the disease was relatively uncommon, and the question may well be asked, why the great increase of diabetes? Blood pressure estimations, while not so general before, have been consistently done during the past twelve years, and yet there is, even in the time elapsing since the influenza epidemic and the present, a huge increase in high blood pressure cases. I have felt that a similar relation may often be made between the influenza and hyperthyroid activity.

How common to hear the statement of the tubercular patient that he has caught a fresh cold, while we smile in a superior sort of way. Often, however, if we watch his temperature and the course of three and a half days of fever, etc., mouth signs, etc., in many instances we must conclude that influenza serves to relight the quiescent Koch.

The present epidemic does not seem so prone to relight tuberculosis as did the 1888 epidemic, yet the history and signs of epidemic influenza, originating afresh or relighting up of a quiescent case, is sufficiently common to arouse one as to its presence, even in the present epidemic.

Among the less lethal disease syndromes that appear to be relighted up by this ubiquitous organism are the following. Many of the periodical attacks of so-called nervous prostration will, if rectal temperatures be taken, show from a half to two degrees of temperature, with characteristic signs of influenza in the mouth. Since noting the connection between attacks of so-called neurasthenia and influenza, the treatment of the latter condition has ceased to be a bore, and it

establishes a new interest in the patient. Especially is this true of the neurasthenia plus weakness developing without cause in a middle-aged or elderly person. In most of such patients the rise in temperature, the eye signs, and a few others will serve to identify the disease. Tonics are wasted on such patients unless they are given after the absolute termination of the disease.

Frequently the story as given is that the patient has had a mild head cold or influenza lasting a few days, and then has developed a complete neurasthenic syndrome, which is charged up to the after effects of the influenza, because the pulse seems normal and the temperature is not taken by rectum but by mouth, and is found to be normal or nearly so. If perchance it is taken by rectum and found to be $99\frac{1}{2}$ or 100, the usual heresy is proclaimed that this elevation is normal and is accepted, and the fact that the patient does not complain of his throat, in fact denies that he has a head cold, induces one to neglect to look into the throat, and so the case is dismissed as being the *after* effects of influenza. Meanwhile, the patient is discouraged, and after trying three or four doctors, about the sixth week falls into the hands of a chiropractor or Christian scientist, and lo, and behold, after a timely visit or two he finds that his sweatings have disappeared, his fears are dissipated, his memory weakness has disappeared, and life again becomes rosy. Who can blame the patient for associating cause and effect? Yet had he been told at the outset of his head cold or influenza that it would take from six to eight weeks before complete recovery would take place, it is not too much to hope that he would have been reconciled to his condition. As it is, he is constantly bemoaning his fate that he did not meet the healer at the beginning of his illness. Incidentally, if I were a chiropractor or healer, I would refuse to take any case until all others had failed, or that at least five weeks had elapsed from the onset, and then glory would be mine.

The presence of the mucous membrane syndrome before an attack of so-called lumbago, before hemorrhoids, phlebitis hemorrhages under the conjunctiva mental disturbances in the aged, as well as at the onset of a host of other disease conditions, may be confirmed by anyone who takes the trouble to look at all of the visible mucous membranes with a critical eye.

I have often felt that an influenza preceded attacks of pyelitis. The objector will say that the same general type of symptoms described as influenza are in a general way present in all infections, and this is true, but here, unlike the other infections, the symptoms never last more than a few days, while the course of the disease is regularly active, in influenza, for three and a half days, and recur for long periods, always indicating their associated mucous membrane fondness, both in the chest and in the mouth.

Many other symptom groups, such as sudden periods of weakness, attacks of dizziness, ill temper, etc., lasting approximately three days, and which occur with some degree of periodicity, and which have often been ascribed to a cyclic cause, have so much in common with the influenza syndrome that a possible connection may at least be suspected.

It is true that there is no certainty as to the agent or organism causing influenza, and one can only surmise its presence by the incidence of the same sort of marks such as occur in the great attacks of influenza, as well as the exact replica of the same in the so-called common cold. How can one distinguish between cold, influenza and grippe when he notes certain mouth signs, presently to be described, in the mouth of the child whose parents assert that he has only a slight cold, yet a day or two later the mouth of his father presents an exact counterpart of the child's mouth, but the father dies in a week or so and the certificate is signed as a death due to influenza.

These signs are as follows

- (1) Injection of the external borders of both conjunctivae,
- (2) Purple lips,
- (3) Enlargement of the mouth of stensons duct and a red puncta at the summit,
- (4) Redness of the anterior pillars of the fauces, either half-way up or encircling the fauces,
- (5) Papules on the uvula,
- (6) Sago grain appearance of upper portion of soft palate,
- (7) Hemorrhagic exudation in various parts of the mouth,
- (8) A rise of from one-half to two degrees of temperature (per rectum)

Closer study of these phenomena inclines one to the suspicion, although not to a certainty, that for the vast majority of people one influenza always influenza. This view is corroborated by the following facts. In a large part of the population the disease regularly recurs every thirty-two to thirty-three weeks, or multiple thereof, occasionally, it recurs at sixteen-week intervals, (2) there is an almost simultaneous attack often of a similar syndrome throughout a large community, often occurring at the same hour many miles apart, where there was no opportunity for contact. These facts will not be noted unless one goes over and checks up accurately the last attack by means of history card. Such recurrences are less severe as a rule in the summer, and for that reason summer rarely causes the filing of a death certificate for a cardiac or a nephritic.

When one asserts that upward of seventy-five per cent of all patients have had well-marked influenza, and that once present they are likely

ever after to remain host to such organism, the objection will be raised that in any event three-quarters of all mouths inspected at any time of the year will show one or more of these signs. This is true in a measure, but in the absence of symptoms of influenza it is uncommon to find three or more signs such as one sees in a frank influenza. This statement may be met with the observation that under certain unknown circumstances and at certain times the mouth and throat infection becomes active and is responsible for symptoms. This may be confirmed by the three and a half day rise in rectal temperature, as well as by the three and a half day run of symptoms, relief and recurrence. This three and a half day temperature is so characteristic that the wonder is that it has not crept more generally into the text books.

In studying head colds, it is interesting to note (1) that the infection may be dormant for a period of one or more weeks before exploding, (2) that a severe spell of three and a half day

fever may occur after two or three weeks of illness, even though the first or second spell of three and a half day discomfort was so slight as to be negligible. Unaccustomed constipation is a quite common symptom in early influenza, (3) the nature of the attack may change, say, at first, being a digestive upset followed by weakness, and on the third or fourth period attack the mucous membrane in the old-fashioned way, (4) that as long as a half degree of temperature lasts the disease is still active, (5) that the so-called post influenzal weakness, etc., really represents a cycle of the active disease itself, (6) that whatever portion of the body is already the seat of chronic disease, that portion is likely to be relighted up by the influenza.

After viewing such a grouping, the natural reaction of the reader is to consider that the author is obsessed with the idea of the universality of influenza, none the less does the speculation become attractive as a solution for age-long problems.

THE MANAGEMENT OF SYPHILIS COMPLICATING PREGNANCY *

By ALFRED C. BECK, M.D.,

BROOKLYN, N. Y.

THIS study is an analysis of 131 pregnancies that occurred in 113 syphilitic women. In each instance the Wassermann was strongly positive on two or more occasions and other unquestionable evidences of syphilis were present. In this review therefore, no cases are included in which the diagnosis was based solely upon the serological findings.

DIAGNOSIS

The history of symptoms and the physical examination were of little service in making the diagnosis. Four patients gave a history of a primary lesion and sixteen described one or more of the secondary manifestations of syphilis. The history itself, therefore, was of value in a total of twenty cases, or 17.7 per cent of our material.

The patient's account of her previous pregnancies was of much greater aid. Seventy-one of the 113 syphilitic women included in this series had been pregnant before. Of these, 45, or 63.3 per cent, had previous miscarriages and stillbirths. Other children were found to have syphilis in 24, or 33.8 per cent, of these multiparae. Contrary to the usual opinion, 26, or 36.6 per cent, had no previous miscarriages or stillbirths, and all of their pregnancies resulted in the birth of living, viable infants. Some of these women had given birth to several full-term living infants which, according to their mother's statement, had always been well. Upon investigation, we learned that most of these children had

syphilis. We, therefore, cannot rule out syphilis when a patient tells us that she has never had a miscarriage or stillbirth, that her pregnancies always went to full term, and that all of her children are living and well. We must rule out congenital syphilis in these children before we may assume that the patient was free from syphilis at the time of her previous pregnancy.

The routine Wassermann test was of inestimable value in our work. Whenever a patient's blood was strongly positive the test was repeated in order that we might eliminate the possibility of a laboratory error. *In our opinion, a strongly positive reaction usually is indicative of syphilis, even though the patient is pregnant.* While we admit that occasionally a patient's blood may be strongly positive during pregnancy and may become negative after delivery, even though no treatment be given. In our experience, however, this observation has been extremely rare. We, therefore, treat all of our cases vigorously whenever the Wassermann is strongly positive, even though no other evidence of syphilis is present, as we have found that investigation of the husband and the other children, as well as subsequent events, usually proves that the patient has undoubted syphilis.

The husbands in twenty-three instances were syphilitic at the time of their wives' pregnancies. In our clinic material, it was extremely difficult to secure the cooperation of most of the husbands. Many of them refused to permit their wives to take treatments or even visit the prenatal clinic after they learned that we had ob-

* From the Department of Obstetrics and Gynecology of The Long Island College Hospital.

tained blood for the Wassermann. Had better cooperation been obtainable, we probably would have found evidence of syphilis in a larger percentage of the husbands.

TREATMENT

As soon as the diagnosis was made, vigorous antisyphilitic treatment was begun, irrespective of the period of gestation. Six intravenous injections of salvarsan were given at weekly intervals. Intramuscular injections of mercury were started at the same time and continued for twelve weeks. If after this course of treatments the Wassermann remained positive, a second similar course was given. Occasionally, the reactions were severe, in which case the dose was diminished.

All infants were referred to the department of pediatrics immediately after birth. They received daily mercury rubs for two months. If the Wassermann was then negative no further treatment was given, unless evidence of syphilis appeared. The infants of the patients who had not received sufficient prenatal treatment and those in whom evidence of congenital syphilis was observed were treated more intensely. In these latter cases, 0.5 c.c. of mercury oxycyanate was administered weekly for six weeks, at the end of which time intramuscular injections of salvarsan were begun.

END RESULTS

In considering the end results, I have grouped the cases according to the amount of salvarsan administered before delivery.

In group (1) the patients received no salvarsan before delivery, 24 cases of this type are included in our study, 12 of these pregnancies resulted in stillbirths, and 7 of the remaining living infants showed evidence of lues, 5, or 20.8 per cent, of the 24 untreated syphilitic women gave birth to living infants, which up to the present time appear to be free from syphilis.

Group (2) contains those cases in which some salvarsan was given, but the total amount was less than that given in our usual course of treatment, 37 patients received from one to five injections of salvarsan, 24 of these gave birth to apparently non-syphilitic infants, 6 pregnancies ended in stillbirths, and 7 resulted in the birth of syphilitic infants. Even in the cases of these seven syphilitic infants the prenatal salvarsan was of distinct benefit, as the congenital syphilis has been easily controlled.

Group (3) is made up of those cases which received six or more injections of salvarsan during pregnancy, 58 of the 70 patients so treated gave birth to living infants which have never shown any evidence of syphilis. (Some of these infants have been under observation for six years.) Of the remaining 12 cases, 6 had stillbirths and 6 living syphilitic infants.

According to this grouping, living non-syphilitic infants were born to 5, or 20.8 per cent, of the

untreated syphilitic women, to 24, or 64.8 per cent, of the inadequately treated, and to 58, or 82.8 per cent, of the 70 well-treated syphilitic mothers.

In a previous report of thirty-two cases the same plan of analysis was followed, and after four years only two changes are required in the end results therein given. In each of these instances, apparently non-syphilitic infants later showed signs of lues. One died of syphilitic meningitis when it was three and a half years old. Prior to the onset of this condition, its Wassermann had been persistently negative. The other showed no signs of syphilis until it was four years of age when its Wassermann became strongly positive. Aside from this sign, no other stigmata of syphilis have appeared. These two most interesting observations lead us to be very cautious as to the prognosis when no stigmata are found during the first few years of the life of a child born to a syphilitic mother. Only careful observation over a long period of time will lead to an accurate opinion as to the prognosis in these cases.

SUMMARY

History and physical findings aided in the diagnosis in only 17.7 per cent of our cases.

Sixty-three and one-third per cent of the women who had been previously pregnant gave a history of miscarriages and stillbirths.

Twenty-six unquestionably syphilitic multiparae carried all of their previous pregnancies to the period of viability and gave birth to living infants (36.6 per cent).

Other children were found to have syphilis in 24, or 33.8 per cent, of the multiparae.

Syphilis cannot be ruled out when a patient states that all of her children are living and well.

The Wassermann reaction is a most valuable aid in the diagnosis of pregnancy syphilis.

The so-called false positive Wassermann due to pregnancy usually is real, and other evidences of syphilis can be found if a careful investigation is made.

Salvarsan should be given as soon as the diagnosis is made, irrespective of the period of gestation.

Even the inadequately treated patients gave birth to a large percentage (64.8 per cent) of apparently healthy infants.

Eighty-two and eight-tenth per cent of the well-treated cases had living infants which have shown no evidence of syphilis.

Prognosis as to these apparently non-syphilitic must be guarded. Two of our infants showed the first signs of syphilis at the ages of three and a half and four years, respectively.

(I wish to acknowledge my indebtedness to the Genitourinary and Pediatric Departments of the hospital for their splendid cooperation in the care of these patients.)

DIABETES MELLITUS—RESULTS OF INSULIN TREATMENT IN A SMALL CLINIC

By G M PARKHURST, M D,

BATH N Y

After the release of Insulin to the profession at large, a small diabetic clinic was organized at the Bath Hospital in order to give our local cases the benefit of Dr Bantings discovery. Many excellent reports and case records have come from the splendidly equipped large city clinics during the past two years. However many localities are not conveniently near such a clinic, and, as the number of diabetics increase, the smaller hospitals and the country physician must meet the question of scientific Insulin treatment. For this reason it has seemed worth while to give a summary of our results and method of caring for these cases at the Bath Hospital.

As a primary step we equipped our small hospital laboratory with materials and colorimeter for doing our own blood-sugar estimations. The necessary equipment for qualitative and quantitative urine sugar and for testing for acetone and di-acetic acid was already at hand. Two of our hospital nurses were given intensive training in dietetics, with special reference to diabetes and were assigned to attend these cases only.

The average stay in hospital for all cases was ten days. A routine blood-sugar was done on admission, to check up the relative severity of the case, and also eliminate a possible renal glycosuria. This initial blood sample was taken one hour after the first measured breakfast. A final blood-sugar was done routinely the day of discharge, the specimen being taken one to two hours after breakfast. Several of the more severe cases had more frequent blood-sugar estimations, but as a routine only the two were done. In addition daily qualitative and quantitative sugar tests were made on the twenty-four hour urine specimen, with tests for acetone and diacetic acid. The aim of treatment was to secure, at discharge, a well balanced diet with twenty-four hour urine sugar free and blood-sugar reading of less than 0.14.

All diets were carefully calculated and measured, the routine initial test diet containing 50 grams of carbohydrate, 1 gram of protein per kilo of patients weight and fat varying from 75 to 135 grams, depending on the amount of acidosis present. The patients were given lectures regarding diet, food values and methods of weighing and calculating their daily quota. In addition a printed booklet containing all this data was given each patient. All cases were discharged with a diet calculated to cover their basal requirement plus 15 to 30 per cent depending on whether they

were returning to a sedentary life or to active work.

Up to February 1, 1924, eighteen cases had been treated, the appended chart showing the grade of severity, diet at time of discharge and present diet, if known, also insulin dosage on discharge and at present time. The present diet is charted as approximate, since practically all cases have lapsed from accurate measuring of foods to the easier method of approximating the amount in household measure. However, this has apparently had no adverse effect, and the figures given for present diet, while not accurate, are probably fairly close to the mark.

The results in our eighteen cases may be summarized briefly, as follows:

(1) Four cases (No 4, 16, 17, 18) have died, two directly from their diabetes. (2) Four cases have passed from observation (No 2, 5, 10, 12), all failing to report after leaving the hospital or at best reporting once or twice. The results in these cases will probably be bad. (3) Three cases (No 6, 13, 15) are listed as showing no change. Their tolerance has not improved and they are existing on the same diet and insulin dose that was given them when discharged from the hospital. Two of these cases were classed as mild and one as severe. None of this group has apparently lost tolerance. (4) Three cases have improved moderately (No 7, 8, 11). Each one of these has been able to keep their original diet or increase it slightly and at the same time reduce their dosage of insulin. This group remain well and sugar free. One case was listed as severe, one moderately severe, and one very severe. (5) Three cases (No 1, 9, 11), have shown great improvement. Their tolerance has increased to such a degree that they have been able to eliminate insulin entirely and are sugar free on an ample but restricted diet. Of these cases two were classed as mild, and one moderately severe. (6) Case 14 has been very unsatisfactory. She has a very severe diabetes, being held sugar free only by extreme dietary restriction (P-54, F-120, C-37), and 20 units of insulin twice a day. However, she constantly breaks over the diet and as a result is gradually going down grade.

Since February 1, 1924, we have had eight additional cases with essentially the same general results. While only one-third of the cases can be rated as improved, no single one who has really cooperated and remained faithful to diet and insulin has lost tolerance so far as we can determine.

RESIGNATION OF THE COUNSEL

Mr George W. Whiteside has resigned as Counsel of the Medical Society of the State of New York in order to enter the firm of Chadbourne, Stanchfield & Levy. He has been the legal advisor of the State Society since September 1, 1920, and has conducted the legal defense of our State members who were involved in malpractice suits. He has guided the officers and

committeemen through the mazes of the laws applying to their official acts, and has been the friend of the medical members of the State Society in the times of their legal troubles. His doctor friends regret his resignation, but congratulate him on the greater opportunities in his new field of work.

THE CORNELL CLINIC

The clinic or dispensary of the Cornell University Medical College conducted in the College building at First Avenue and 27th Street, New York City, is designed to give medical service on a self-supporting basis to persons of moderate means. It is commonly known as the Cornell Pay Clinic, because it charges a dollar and a half per visit instead of the usual maximum of twenty-five cents for free dispensary service. It was opened in its present form on November 1, 1921. In three full years of its operation it has received 54,535 patients, who made 340,796 visits, and paid \$650,747 in fees. The Clinic was operated at a deficit of \$84,051. Information regarding the Clinic is contained in two annual reports, and in a report of an investigation of the Clinic made by the Committee on Dispensary Development of the United Hospital Fund of New York—which Committee had underwritten the deficiency in the operating expenses of the Clinic. These three reports fill about 125 pages with interesting reading.

The basis of admission to the Clinic is that the family of the patient must have an annual income ranging between \$1,100 and \$3,000, according to the number of dependents in the patient's family, and the probable number of visits which will be needed. If, for example, a single man with no dependents will require a considerable number of treatments, he will be accepted if his income is not less than \$1,100 or more than \$1,800. If it is less than the lower limit, he is referred to a free dispensary, and if more than the upper limit, he is referred to a physician as a pay case.

The objects of the Clinic, as stated by Dr. Walter L. Niles, Dean of the Medical College, are:

"1 To improve the facilities for the instruction of students, and for scientific purposes.

"2 To assist a large class of persons who, it was believed, existed in the community, who can pay something for medical services, but not the rates usually charged in private offices, particularly when the service of specialists or expensive diagnostic work is required."

Dr. Niles states that the underlying principles of operation have been:

"1 To render the best possible service.

"2 To pay the entire staff, medical and non-medical, for services rendered.

"3 To charge fees which will exactly meet the cost of such services."

The point of view of the physicians of New York City is that the Cornell Clinic is practicing medicine among a class of patients who can pay for medical services, and to that extent is competing with physicians in private practice. The questions of medical ethics and of advertising are also mentioned. In order to understand the viewpoints of both the physicians and the Medical College, the relation of general practitioners to

their patients must be studied. An excellent presentation of this subject is that by Dr. Frank Billings of Chicago, in an article entitled, "The resourceful General Practitioner of Modern Medicine" published in the *Journal of the American Medical Association*, February 24, 1923. The article closes:

"The American family home has been and must continue to be the very foundation of this nation. Bolshevistic socialism, anarchy, and public discord cannot exist in a nation of family homes. The integrity and perpetuation of this nation are dependent chiefly on the maintenance of family life, and the continuance of the family home demands the preservation of the family physician, the general practitioner."

A general practitioner is not expected to know everything about every patient, but Dr. Billings says:

"A diagnosis can be made in fully 80 per cent of all cases by a resourceful general practitioner who will efficiently use his brain, special senses, hands, and an always available simple and inexpensive laboratory and instrumental equipment. He (the general practitioner) should possess and use in routine practice a simple chemical equipment and standardized urinometer for urinalysis, a microscope, blood counter, hemoglobinometer, rectal, aural, and vaginal specula, laryngeal mirrors, head mirror, blood pressure instrument, stethoscope, stomach tube, and an electric light device for transillumination of the accessory nasal sinuses, jaws, and other tissues.

"For the few patients who require laboratory or instrumental tests which involve special knowledge and technical skill in their application, the practitioner should make use of the excellent commercial laboratories, public clinics, and available state, county, and municipal public health laboratories.

"The interest in pathologic physiology has resulted in the elaboration of laboratory and instrumental functional tests in diagnosis which require such technical skill and experience in their application that they are valueless to the general practitioner. Fortunately, these requirements in functional diagnosis are not needed in more than 20 per cent of the patients in any community."

Dr. Billings provides a standard by which the medical profession may estimate the value of the Cornell Clinic. He estimates a considerable proportion of the cases of a family physician—15 or 20 per cent—require more extensive study than a family doctor can give. Patients may be divided into three classes in regard to their ability to pay for the extra services. Those who are well-to-do will pay in full as the physician may charge. The poor will pay nothing, and will patronize dispensaries and hospitals.

The third class consists of those who will pay

for ordinary calls in acute illness, but cannot meet the expenses of a prolonged sickness or of extensive laboratory tests, or a specialist's fee. It is this third class of persons that is the peculiar field of the Cornell Clinic.

The Clinic can render special service to physicians. According to the reports of the Clinic, it has ministered to 7,044 cases that have been referred to it by 2,779 physicians. About thirteen per cent of its cases are those which have been referred to it by physicians. Physicians recognize the value of this service to both themselves and to their patients.

Thirty-seven per cent of the cases that are treated at the Clinic claimed that they had not consulted any physician for their present trouble. This may be interpreted to mean that while some of them may have sought medical advice for some of the symptoms, the doctors have not gone beyond a symptomatic diagnosis. The patients, for example, may have gone to a doctor complaining of "indigestion," and have refused to submit to a thorough physical examination which would have revealed incipient tuberculosis or an infected gall bladder, or chronic appendicitis. The whole truth in these cases is difficult to ascertain, but the evidence inclines one to the opinion that the patients approximate the truth when they say that they have not consulted a doctor for the condition that is diagnosed by the Clinic after a complete examination. It would seem that the Clinic is justified in taking these cases, especially when we consider the public health value of the education of this large number of patients who thereby gain a new viewpoint regarding scientific medicine. These patients would likely be inclined to cooperate with private physicians in the future.

Four per cent of the cases have been under the care of irregular practitioners. The Clinic probably gives these patients a new viewpoint regarding the value of the service which a family physician can render.

The relations of the remaining forty-six per cent of the cases to the medical profession are difficult to estimate, but it is fair to assume that many of them would name a physician as their own if they were required to do so. Evidence that this is so is afforded by the experience of examining physicians in county tuberculosis sanatoriums, who conduct clinics in accordance with the ethics of medical societies. When these physicians examine a case in a clinic, they require the patient to give the name of his family doctor, and if he has none, to choose one. The examiner then sends the report of the case to the doctor, and requires the patient to go to that doctor for information regarding his case. Patients usually name a doctor when the situation is explained to them. The Cornell Clinic also could probably get nearly every patient to name a doctor.

The County of New York has two great medical societies—the County Medical Society and the Academy of Medicine. These are the official representatives of the physicians of Manhattan, and everything relating to medicine in the County is their concern. The Cornell Clinic cannot now retrace its steps and secure the advice of the societies as to how the Clinic could best be planned and established. But is it not possible that the societies could be represented in all matters in which the Clinic is related to the practicing physicians?

There is a growing feeling among doctors that the official organizations of physicians should be consulted in every matter relating to public health. There is also an increasing willingness and desire on the part of doctors to do their share in every phase of the practice of civic medicine. Is it too much to suggest that the Medical Society of the County and the New York Academy of Medicine of New York could co-operate with the Cornell Medical College in working out a plan for conducting the Clinic to the satisfaction of both the medical profession and the College?

SOFT COAL SMOKE IN NEW YORK CITY

Does soft coal smoke concern physicians? Any one living in New York City will necessarily be concerned with the pall of sooty smoke that hangs over the streets, be he physician, or pastor, or common laborer. The laundryman and the window cleaner profit directly, the pastor is alarmed over the increase in profanity, the calls on the throat specialist are increased, and the business of the cough-drop manufacturer is boomed.

New York City, the long-suffering, accustomed to the bad air of subways, to the crowding of the elevateds, to the hurry, and the multitudinous discomforts of life, is strangely patient under the sooty fog, and seems to regard the smoke as merely another annoyance that produces new

thrills, rather than disables anybody. The people of New York are at the same time the most nervous and the most self-controlled of all the Nation. For them the sun always shines behind the smoke cloud, and electric lights readily dispel the gloom, and cold cream the grime.

New York is the Nation's greatest health resort. Its environmental conditions that really affect health—water, food, and sewage—are safe, and in these days, they never produce an epidemic. New Yorkers have full confidence in their physicians and Health Department to protect them from preventable sickness, and they make no complaint about the smoke unless it becomes unbearable.

PREVENTION OF DIPHTHERIA

The prevention of diphtheria is one of the most important modern problems in public health. The available knowledge concerning diphtheria is greater and more complete than that regarding any other communicable disease, and is amply sufficient for almost universal protection against the disease. Not only is there an available serum for curative and preventive purposes for immediate use in the face of danger, but toxin-antitoxin is available for producing a lasting immunity in practically all persons to whom it is given.

The great public health forces of New York State are uniting in a campaign for the immunization of all children with toxin-antitoxin during the next year or two. There are three great organizations, or rather groups of organizations, who are joining in this campaign. First is the Department of Health of the State and of New York City, together with the one thousand or more boards of health of the local municipalities.

Second is the great group of lay organizations that are interested in public health, especially the tuberculosis and public health committees of the several counties.

Third, there is the medical profession, represented by the Medical Society of the State of New York, the county medical societies, and the academies of medicine.

The Departments of Health of the State and the larger cities have demonstrated the practicability and effectiveness of toxin-antitoxin over a period of a dozen years or more. They have standardized and simplified the methods of its administration, and have made its use as easy as the injection of a dose of any other substance hypodermically. They have demonstrated that family physicians can give injections with ease and safety. They have subjected the procedure to tests under every conceivable condition, and are prepared to give it their unqualified endorsement.

The great work of the lay organizations is that of educating the people regarding the immunizations, their value and their safety. School children have been the group in which the greatest number of immunizations have been given, and the teachers, school nurses, and parent teachers associations, and similar societies, have been the principal organizations that have secured the parents' consents for the injections by health officers and school physicians.

The people in the cities and villages have been well instructed regarding toxin-antitoxin, but those in smaller villages and the rural districts are still largely uninstructed regarding the immunity. The instruction of these people is the work of the county tuberculosis and public health

organizations that exist in nearly every county of New York State. These organizations can also provide the financial means for carrying on the immunizations among those who are unwilling or unable to pay for them.

Family physicians are the group on whom the responsibility for giving the immunizations must ultimately fall. Children reach the age of seven years, or the lowest school age, before they receive the benefit of toxin-antitoxin under the present system. There is no ready way of reaching children of the pre-school age, except through their family doctors.

Why are doctors not giving toxin-antitoxin as a routine measure? Among the reasons conservatism and inertia are prominent. A campaign of inspiration is needed in order to arouse the doctors to engage in that form of medical practice as a part of their duty to the families in their care. The customs of medical men are opposed to the idea that they shall plead with people to adopt a medical measure, no matter how good it is. However, a doctor at present is entirely justified in offering the service to his families, and he is not justified in neglecting to provide himself with the material for giving the injections to those who wish them.

Diphtheria immunization has been the subject of several conferences between the representatives of the State Department of Health, the leading lay organizations, and the State Medical Society, with the object of securing the cooperation of the three great groups of organizations along the lines that have been indicated. Each group has its own definite work to do, and if each does its part, it may be possible to realize the ideal set by one lay organization: "No more diphtheria by 1930."

What is the part of physicians in this new movement for the eradication of diphtheria? The movement started by the State Medical Society may properly be taken up by the sixty county medical societies. The leaders in each county society understand medical conditions in their community, and can best arrange the details of a campaign to arouse the interest of the members of the societies. The first step would probably be to promote the immunizations of school children. When the school children have been immunized, it will be a natural step for the doctors to immunize the children of pre-school age.

The conferences on diphtheria prevention constitute a wonderful work of progress in securing cooperation by the three great groups of the promoters of public health. It is to be hoped that the work so well begun will be extended to other fields of medicine.

THE ALTRUISTIC SERVICE OF THE HEALTH OFFICER

Over ten per cent of the physicians of New York State, outside of New York City, are health officers, and over seventy-five per cent of the health officers are active members of the Medical Society of the State of New York. It is therefore of direct interest to a large group of physicians to consider what Dr Matthias Nicoll, Jr, State Commissioner of Health, said about the rewards of health officer service in an address before the last meeting of the American Medical Association which was reported in the *1 M A Journal*, November 14, 1925, under the title, "Some Problems in Public Health Administration." Dr Nicoll said:

"Official health work, fully entered in, by no means enhances the prospects of success in medical practice, but, as shown by experience, actually decreases it. In this respect, the health officer's position is quite unlike that of other administrative officials, whose tenure of office usually entails little or no sacrifice of business or profession. Indeed, many of them derive much benefit from the reputation and association afforded by public service."

Any one who attends the annual conference of health officers of New York State will be impressed with the high medical standards and public spirit of the five hundred health officers in attendance—nearly as many as the number of doctors attending the meeting of the State Medical Society. All these health officers know the truth of what Commissioner Nicoll says about the rewards of health officer work.

Why should any group of physicians practice public health at a personal sacrifice?

What is wrong with a governmental system that penalizes a doctor for performing a necessary public service?

In order to discuss the answers to the two questions intelligently, one must understand the organization of a local health department and the statutory duties of a health officer.

The Public Health Law, Section 21, says that "the local board of health shall direct its health officer in the performance of his duties," and "the health officer shall be the chief executive officer of the board."

The law divides a health officer's duties into two classes: 1, those relating to communicable diseases or the control of all persons and things infected with or exposed to such disease, and, 2, those relating to environmental conditions, such as sewage, water supplies, and the great number and variety of annoying conditions called nuisances.

The Public Health Law, Section 25, places the control of communicable disease matters jointly with the board of health and the health officer, while Section 26 places the control of environmental conditions with the board of health only.

It will thus be seen that the law makes the board of health the supreme power in health matters. A health officer gets into trouble when he attempts to perform the duties that belong to a board of health.

A health officer has two classes of duties to perform as the executive officer of a board of health: 1, scientific, and, 2, police.

The health officer is the advisor of the board in all matters medical and sanitary. He investigates conditions, makes diagnoses, and gives professional advice to the delinquent parties and to the board of health.

If the delinquents fail to act upon the advice of the health officer, then police power may need to be used to compel obedience to the advice.

It is not the duty of a health officer to use police power. That duty belongs to a board of health, and through it to the department of police or of law. Most troubles and annoyances and ill-feelings encountered by a health officer arise from his attempts to perform police duty—a duty which does not belong to him. While politicians are prone to interfere in police duties of a health officer, they hesitate to go contrary to his professional advice. A wise health officer will stick to his professional duties and let the board of health attend to the police duties.

The two questions asked at the beginning of this article may now be answered intelligently. Health officers should not practice public health at a personal sacrifice, and they need not do so if they confine themselves to medical activities and leave police duties to boards of health.

AN APOLOGY

To err seems to be the unexpected lot of all mortals. To guard against mechanical mistakes in printing is the duty of editors, but after all page proofs are read and re-read by the editors, the final make-ready is entrusted to the employees of the printers. The editors regret exceedingly that in finally locking up the forms, the make-up

man crowded two adjoining editorial columns together on the top of page 69 of the last issue, so that no space was left between them, and the lines appear to run completely across the page.

The editors offer their humble apology and explanation to the readers for this last-minute mistake of the printers.

THE ANNUAL MEETING

The Annual Meeting of the Medical Society of the State of New York must necessarily be held on an unusually early date in order to elect delegates at least two weeks before the meeting of the American Medical Association, which will be held April 19-23 in Dallas, Texas. The State meeting will be held March 29-April 1 in the Hotel Waldorf, New York. The hotel affords ideal accommodations for the State Society, as those can testify who have attended the meetings there in previous years. The popularity of the meeting place is shown by the eagerness of the exhibitors to obtain space.

This year's meeting promises to be one of the most interesting that has ever been held. The scientific programs are being developed and plans are under way to hold an exhibit in a specialty

after the plan which was so successful last year in the subject of tuberculosis.

The months which have elapsed since the last annual meeting have been packed full of activities of a wide scope, among which that of graduate education is an outstanding new feature. The stimulating effect of the inspiring work of the Committee on Public Health and Education has been felt in every county medical society, while that of the Special Nursing Committee promises to settle the vexed questions of the efficient training of a sufficient number of skilled nurses to meet the increased demand for the care of the sick as well as to supply the thousands of nurses who are required in the ever-increasing field of public health nursing. The reports of the committees to the House of Delegates will undoubtedly be of greater interest than ever before.

PHYSICIANS' DUTY TO THE COMING LEGISLATURE

Physicians have spent much time and money in finding out that they cannot compete with practical politicians. What they have accomplished has not been due to any political skill or power, but to the respect in which they are held as doctors. Much has been said about what the sixteen thousand doctors of New York State *could* accomplish if they would vote as a unit, and get all their friends and patients to do the same. The fact remains that physicians will not enter the arena of politics, and by the weight of their numbers compel any body of men to adopt a policy which may be reversed at any time that a slight majority becomes a minority. The policies of one set of politicians are in effect so long as fifty and one-tenth per cent of the votes are cast for those politicians, and the opposite policies are in force when one voter in a thousand changes his mind. It is on such extremely slight changes as these that success in any political field often hangs.

It is not to be inferred that doctors have no

influence with members of the Legislature. On the contrary, they have more influence than they suspect. The Legislators know them as men of wide knowledge, good judgment and public spirit. When two or three doctors call on a legislator, and state their arguments, they receive respectful attention, and when a legislator is invited to a meeting or dinner of a medical society, he is deeply impressed.

Is it the work of physicians to secure a flood of telegrams and letters and conduct hearings in support of their measures?

Is it not rather the work of physicians to state the ideals of the profession and the arguments for their adoption, and then leave to the legislators and lawyers the details of making and passing the laws?

While physicians hesitate to overwhelm legislators by political methods, they will always be ready to advise and inform the lawmakers on all medical matters relating to the public.

LOOKING BACKWARD TWENTY-FIVE YEARS AGO

The New York State Journal of Medicine for February, 1901, contains a news item which throws light upon the evolution of health regulations regarding pure milk. "A case of some importance was recently non-settled in the Supreme Court of the Rochester district. A milkman had been using formaldehyde for the preservation of cream. A sample of this cream was taken by the State Department of Agriculture (and found to contain) formaldehyde, approximately more than 1 in 50,000 parts. The law under which this case was brought provides that no unwholesome, impure or adulterated milk shall be sold.

"The plaintiff sought to prove his case by showing the harmful effects of formaldehyde. The judge held that, while experiments (regarding the harm) were most interesting and instructive, the plaintiff had not proven his case, in that he had failed to show that the defendant had the cream and formaldehyde in his possession.

"The interest in the case was chiefly in the fact that it was not defended by the milkman against whom it was really brought, but by a large manufacturing firm selling formaldehyde under the name of a milk preservative, and thus, if the decision stands, will be able to sell its product without hindrance."

MEDICAL PROGRESS

Lipiodol in Radiodiagnosis—Since its introduction a few years ago as an opaque filling material in x-ray examinations, the use of lipiodol has been increasingly evident. It was employed three years ago by Sergeant for the localization of spinal cord lesions (*Proc Royal Soc Medicine*, December 1, 1922). Between 1 and 2 c c of lipiodol is injected into the spinal theca through a suboccipital puncture, the patient being in a sitting posture, the fluid slowly descends until it meets the point of occlusion in the theca, where it is arrested thus defining the upper limit of the tumor. Similarly, the lower limit of the tumor may be mapped out by the arrest of the fluid injected through a lumbar puncture. In a later paper (*British Medical Journal*, 1924, 1, 716) Sergeant said that, with further experience, he considered this method as one of great value and had never had any bad results from its employment. Radovici, Dragonesco, and Georgesco (*Bull et Mem, Soc Méd Hôp de Bucarest*, 27, 1924) report 10 cases in which this method was used with no harmful results. In 4 cases a diagnosis of cord compression was confirmed, in 3 they were enabled to exclude subarachnoid compression which had been diagnosed clinically, in 3 the diagnosis of myelitis without compression of the cord was confirmed.

A. S. Maclaire of New York, on the other hand, has had an unpleasant experience in a case which leads him to the belief that the substance is distinctly irritating to nerve tissue (*Ann Journal of the Medical Sciences*, December, 1925, clxx, 6). The patient was a man aged 37 years, who had had difficulty in locomotion for two years, due apparently to cranial and vertebral injuries sustained eighteen years previously. As a diagnostic measure, lipiodol was injected through both cisterna magna and lumbar punctures. The pre-operative diagnosis was compression fracture of the fourth dorsal vertebra with meningo-myelitic adhesions extending from the eighth to the eleventh dorsal segments. Laminectomy was performed. Five months later the patient returned in a markedly worse condition. A second laminectomy revealed recent dense leptomeningeal as well as meningo-myelitic adhesions, the arachnoid was much thickened, and there was no question that the damage to the tissues had been produced since the last operation. Two arachnoid cysts, one the size of a green pea and the other the size of a kidney bean were found lying opposite the tenth dorsal segment, these contained lipiodol. The results in this case have led the author to abandon the use of lipiodol as a localizing agent in spinal

cord affections. A similarly unfavorable opinion is expressed by William Sharpe and C. A. Peterson (*Annals of Surgery*, January, 1925, lxxxiii, 1) who, believing that the injection of lipiodol into the spinal theca was a harmless method for the localization of spinal block, employed a chemically pure preparation of this substance in three patients. The results were of definite diagnostic value in all cases, but in one case an inflammatory reaction occurred at the site of the arrested lipiodol, the symptoms becoming aggravated to a degree necessitating the removal of the lipiodol at a later laminectomy. Roentgenograms of all three patients revealed unabsorbed lipiodol in the spinal canal, even after an interval of fifteen months following the injection.

Armand-Delille, Duhamel and Marty (*Presse Médicale*, May 14, 1924) called attention to the great value of intratracheal injections of lipiodol in the differential diagnosis of bronchiectasis, basal tuberculosis, pulmonary abscess, and interlobular empyema. The oil is injected by means of a curved trocar and cannula introduced through the cricothyroid membrane. The injection is made under local anesthesia with the patient recumbent. The material does not clog the bronchial tubes, being promptly expelled by coughing as the anesthesia of the trachea wears off. Quite minute dilatations of the bronchi are made visible by this method.

The injection of lipiodol in the diagnosis of bronchial lesions suggested to Carlos Heuser (*Lancet*, November 28, 1925, ccix, 5335) the use of the oil in the diagnosis of pregnancy prior to the fourth month. The technique consists in giving a laxative and, four hours before making the roentgenogram, 20 or 30 drops of laudanum, in order to keep the patient quiet. The vagina is cleansed with formalin soap, the neck of the uterus is brushed with tincture of iodine, and under the most careful antiseptic precautions a metallic cannula is introduced into the uterine cavity until the Bandl ring is passed. Then 1 to 2 c c of lipiodol is injected. The roentgenogram is now taken, and, if possible another 2 to 5 c c of lipiodol is injected and a second roentgenogram is made. The liquid is used warm, without employing much force, and without moving the cannula within the uterus. The lipiodol runs over the uterine walls and penetrates into the tubes if these are free. When the injection has been successfully made, the oil seeps around the fetus, the roentgenogram showing the cavity is occupied. When the fetus is larger, the liquid penetrates very little and in a more or less curved line. If the patient

is not pregnant, the injection of lipiodol will reveal the uterine cavity of triangular shape and at the same time one or both tubes may fill up with liquid. The roentgenogram also makes possible the diagnosis of sterility due to obstruction of the tubes, for it may be observed that they do not fill or fill badly. The injection of lipiodol into the uterus will not cause abortion if proper precautions are observed.

The Surgical Treatment of Bronchial Asthma.—Fukujiro Ishiyama (*Japan Medical World*, October 15, 1925, v 10) reports two cases of bronchial asthma treated by resection of the cervical sympathetic ganglion, in both of which, during the first week after operation, there was marked improvement in the respiratory condition. Within ten days or two weeks, however, the condition was aggravated and there were attacks as before the operation. The author then resorted to Freund's operation, which is based on the fact that in the majority of cases of so-called bronchial asthma, the chief complaint of which is the respiratory difficulty, there is emphysema, and as a result marked distention of the chest wall. This condition naturally hinders recovery from the respiratory difficulties. In order to cure the condition radically the abnormal contraction of the smooth muscles of the bronchi must be overcome so as to allow the lungs to inspire fully. To this end freedom of movement of the chest wall is an important factor. Freund's operation, which consists in the removal of the costal cartilages from the second to the fourth or fifth, relieves the distention and makes movements of the chest wall easier. In seven of eight cases thus treated, complete relief was afforded, and the beneficial effects became more marked as time passed. One patient, however, died of cardiac paralysis soon after the operation. This method of treatment is, of course, merely symptomatic.

G. Hofer, writing on sympathectomy in the *Wiener medizinische Wochenschrift* for October 31, 1925, says that the operations proposed for the relief of bronchial asthma are in need of a searching critique, for it is manifestly difficult to be sure that the operation has caused the disappearance of symptoms when this sequence occurs, since long spontaneous intermissions are not uncommon. From another angle, supposing that the operation of sympathectomy, for example, has succeeded, the asthma may reappear as a result of an intranasal lesion or of anaphylaxis. In the case of nasal asthma an intranasal operation may bring relief but some other factor may start up the patient's difficulty of breathing and Sauerbrush has, at least temporarily, ceased to recommend operation for this condition. Should surgery prevail in these cases it will mean the confession that asthma is largely beyond the resources of the physician. The selection of cases

of asthma which will presumably be amenable to surgical relief must be even more difficult than in the case of angina pectoris.

The Pyretic (Malarial) Treatment of Syphilis and Metasyphilis.—Nonne, the well-known authority on syphilis of the nervous system, has made his contribution to this subject, having now treated about 450 paretics in this manner, with 30 cases of tabes. He discusses (*Medizinische Klinik*, December 4, 1925) the results obtained in 322 followed-up cases of paresis, of which he has cured 30 per cent or nearly 100 individuals now in good mental health and able to support themselves. He does not think that these subjects are liable to relapse. At first he regarded as prognostically more favorable the cases which began with excitement, but at present he includes cases with initial dementia as well, provided treatment is instituted early. This latter is of the greatest influence on prognosis in all patients—the earlier the treatment the better the outlook. Dementia cases of long standing should not be treated at all and in many paretics the resistance is too low for such vigorous treatment although the author gives us no standards of resistance as a guide, nor does he state whether these cases can be recognized before the treatment is started. A paretic inoculated with malaria must be regarded as a very sick man. The author's death rate is low—8 per cent for the 322 cases and none from malaria or even directly from syphilis. Only a pure tertian strain should be used for inoculation and blood tests should be made daily. Flooding of the blood with the malarial parasites shows that treatment should be broken off. No patient is discharged until his blood has been free from parasites for at least three weeks. Quinine, in addition to its control of malaria, exerts a salutary influence on the paresis.

It was inevitable that the success of the malarial treatment of metasyphilis should be an incentive to extend the use of the resource to ordinary syphilis. Scherber has now been experimenting along this line for several years (*Wiener medizinische Wochenschrift*, December 5, 1925). Thus far, however, he has not gone very far away from the treatment of nervous syphilis, meaning by this term the presence of a positive seroreaction in the cerebrospinal fluid. The use of the malaria virus is much preferred over any other form of pyretogenic medication, so that fever treatment becomes synonymous with malaria treatment. Important contraindications must be borne in mind and the author would not use the treatment in any one over 55 years of age. It is contraindicated by any cardiovascular lesion and hence holds out no hope in aortic syphilis. In any case the method is not to be used in a routine way, for it is not only advisable but absolutely necessary that the patient shall have received previously all of the benefit

he can from salvarsan, bismuth, etc. If the disease continues to relapse despite the drug treatment, or if there is a positive spinal fluid reaction or only an unchangeable and strong positive blood reaction he would interpolate the malaria treatment and afterwards resort again to the drug treatment. He would on no account begin treatment with the malaria virus, for in two instances, he noted after this procedure, the development of peculiar periosteal nodes which he attributed to some mobilizing action on an old focus of spirochetes. The treatment largely resolves itself into a cure of such neurotropic cases as might be predisposed to develop metasyphilis. (See also this JOURNAL, January 1, 1926, p. 29.)

Is There a Special Strain of Treponema in Syphilis of the Nervous System?—The view that the cause of nervous syphilis is distinct from that of ordinary syphilis is by no means recent and in fact was first suggested by Morel-Lavallée in 1888, many years before the discovery of the treponema. Following the discovery of *Treponema pallidum*, the theory was propounded of a special neurotropic strain of the microorganism which is responsible for the nervous lesions of the disease, whether these are syphilitic or metasyphilitic. With this theory in mind, Sézary has made a study of conjugal neurosyphilis. He points out that it is not very rare for both spouses to develop neurosyphilis in some form such as meningitis, hemiplegia, paralysis of the cranial nerves or progressive paresis and tabes. The term neurosyphilis is, however, loosely used, for hemiplegia, since it follows an arterial lesion, might be relegated to the group of vascular syphilis, and a similar objection could be lodged against specific meningitis as not originating, strictly speaking, in nervous tissue. Since in conjugal neurosyphilis there are children born after infection of the parents, it should be a simple matter to decide the question by studying the lesions of the inherited cases. While it is true that Nonné has cited a case in which the child also showed neurosyphilis, Margeridon has quite recently demonstrated a similar case in which the child showed numerous ordinary lesions of hereditary syphilis, with the nerve centers quite immune. We overlook the thousands of wives of tabetics, paretics, etc., who show no evidence of neurosyphilis, although evidently infected by their husbands. Again, in a certain number of these cases of alleged neurosyphilis, we find aortitis or late lesions of the skin or mucosæ which cannot be explained by the doctrine of two strains of treponema. Since no other alternative can be even plausibly suggested, the author thinks we shall have to explain conjugal neurosyphilis by simple coincidence, although no figures can yet be quoted to clinch this belief.—*La Presse Médicale*, November 14, 1925

Present Status of the Treatment of Pneumonia by Diathermy—Reviewing his four years' experience in the treatment of pneumonia by means of diathermy, Harry Eaton Stewart (*Clinical Medicine*, December, 1925, XLII, 12) states that he has given some 2,400 treatments without an untoward effect. The application of diathermy brings immediate and almost invariable symptomatic relief, lasting from two to four hours. It may safely be repeated at four hour intervals, although three treatments a day will usually suffice. The average death rate of the treated cases to date was 13.6, while that of the different series of controls ranged between 25 and 42.9 per cent. There is thus an apparent lessening of the mortality, this point will doubtless be definitely established in the near future by reports of sufficient additional cases. Following treatment with diathermy there is usually a fall in temperature by lysis, in only four or five cases in the entire series was there a fall by crisis or semicrisis. The treatment consists in the application of the d'Arsonval bipolar high frequency current directly through the affected area, by the anteroposterior route. The maximum current used is 1,400 to 2,000 ma, five minutes is consumed in reaching this maximum, which is maintained for 20 to 30 minutes. The current is applied by means of flexible plate electrodes about five by seven inches in diameter. Except for the first treatment a somewhat lower amperage is employed—1,200 to 1,400. In streptococcal and other pneumonia there has been only clinical relief, with no apparent reduction of mortality. Postinfluenzal pneumonia of the type that followed the 1918 epidemic has not responded well, although the dry lobular type seen last year was apparently benefited by this treatment.

Lumbar Puncture Headache—The fact that there seems to be no way to predict whether headache will follow lumbar puncture, and no method of treatment when such a complication is suspected, has led Bernard J. Alpers (*Archives of Neurology and Psychiatry*, December, 1925, XIV, 6) to investigate this subject. Observations were made on 91 patients at the Boston Psychopathic Hospital. Lumbar puncture was performed in the usual way and the patient was observed during a period of ten to fourteen days. Large amounts of fluid were removed in order to determine the effect in the production of headache. Of the 91 patients, 16 developed headache. In those cases in which a postpuncture headache occurred there was a marked fall in the spinal fluid pressure after lumbar puncture and the withdrawal of fluid. The conclusion to be drawn is not that in cases with a low initial pressure postpuncture headache is likely to develop, but rather that in cases with a notable disturbance in pres-

sure relations, as indicated by a decided fall in the spinal fluid pressure, a reaction will probably develop. It therefore seemed rational to treat these patients by an attempt to increase the spinal fluid pressure. This was done by the use of pituitrin given intramuscularly (1 cc) and a hypotonic salt solution given intravenously (usually about 100 cc of a 0.5 per cent solution of sodium chloride). In severe cases of lumbar puncture headache, the use of hypotonic salt solution is more beneficial than that of pituitary extract, and the effect on the spinal fluid pressure is also more lasting. The size of the needle is probably an important factor in determining the amount of leakage of spinal fluid. A very fine needle should be used and patients should be kept in bed for 24 to 48 hours, with the head low.

Tobacco Treatment of the Tremor Following Encephalitis Epidemica—Herrmann and Wotke, writing in the *Medizinische Klinik* of December 4, 1925, relate their experience with nicotine in the treatment of the post-encephalitic tremor so often encountered in the somnolent form of the disease. It has long been known that in some patients the smoking of a cigar or even a cigarette will bring these trembles to a stop. The authors therefore, with this aim in view, tested nicotine in the anticipation of a more striking and protracted effect. The tartrate of the alkaloid was first tested intravenously and found in safe dose to be inferior to smoking. Next a decoction was made from cigarette tobacco and the results were found to be equal to or superior to those of the act of smoking. There were two sets of results according as the patient was or was not acutely poisoned by the tobacco. In the mild case the benefit lasted from a few minutes only to several hours, and in some patients there were no results at all. When tobacco was given in toxic doses the effects were much more pronounced, lasting from several hours to 20 days. The safe dose of the extract is from one-tenth to one-fifth of a gram. No practical conclusions are drawn and it would seem as if smoking—or possibly chewing—tobacco is the more practicable way of exhibiting the remedy, even if less powerful than tobacco extract.

The Under-Rested Child—Robert Ewart Ramsay (*Archives of Pediatrics*, December, 1925, xlii, 12) discusses the problem of the restless, crying, peevish, unmanageable child, who is suffering from lack of sleep and rest. Failure to obtain sufficient rest in an age so full of shocks and wonders is sufficient explanation for much that passes by the name of malnutrition and nervousness. The well-defined signs of failure to secure adequate rest and recuperation are failure to gain in weight, fatigue posture and irritability. When in a case of failure to gain in weight, gross errors in diet and hygiene and

gross physical defects have been excluded, it is justifiable to consider lack of rest as a factor. In the treatment of these cases it is usually sufficient to prolong the hours in bed (7 P. M. to 10 A. M.), shorten the hours of school work, limit the amount of strenuous play, enforce a plain and unstimulating diet, enjoin fresh air and pure water. A plain, bulky, nutritious diet, avoiding the concentrated rich foods, especially meat and eggs, will be better handled, promote elimination, and build up a normal appetite. The use of tonics has no place in the treatment of the under-rested child. The maintenance of the fatigue posture over any great length of time constitutes a menace to the health of the child. For the correction of faulty posture, daily building-up exercises should be instituted. The third characteristic of the under-rested child, namely, irritability, is too often fostered by trying to please the child by the multiplication of amusements and distractions. Excitement does not need to be forced upon any child, the developing mind of the child supplies its own excitement. The unstable nervous system of the child needs prohibiting and even subduing influences—a quiet bedroom, sleep in the dark, meals in quiet, toys and books provided but not forced, and protection from admiring friends and doting relatives.

Complexion and Constitution—Ascher writes of the relationship of pigmentation to the physical and mental constitution. Now that the old pseudo science of the somatic and psychic interrelations of mankind has undergone rationalization, it is recognized that the physique not only plays a predisposing role in disease states, as has long been shown, but is of influence on temperament and even character. It should, therefore, be possible to correlate the complexion with the predisposition to disease, the physique, and the mental and character equipment. The author speaks of the three grades of fair, medium and dark skins, hair, and eye color, and associates these with disease and temperament. He cites a few examples, as the delicacy of the skin and mucosæ of the blonde, the pungent secretions and richer milk of the brunette, the predisposition of the dark to liver disease and renal calculi, the relative sexual frigidity of the blonde as compared with the brunette, etc. But even without any special research, it should be possible to add greatly to such data from common knowledge, although some axioms may never have been scientifically verified. Thus, the red-head is commonly believed to be more subject to infections, a florid complexion is often regarded as an unfavorable prognostic sign in early tuberculosis, and red hair is thought to be associated with a quick temper. In races of mixed complexion, the black-eyed are always accused of being more mercurial, passionate, vindictive, etc., than the light-eyed—*Arch. f. Frauenkunde*, vi, 4-5 1925.

LEGAL

By LLOYD PAUL STRYKER, Esq

A BILL TO LICENSE CHIROPRACTORS TO PRACTICE MEDICINE

Every chiropractor in this State who has not been legally authorized to practice medicine, but who has in any way treated or prescribed for any human disease, pain, injury, deformity or physical condition, or who has held himself out as being able to do so, is a lawbreaker. The penal statute which he has flouted and defied is Section 174 of the Public Health Law, making it a crime punishable by imprisonment or fine, or by both, to practice medicine without a license.

More than eleven years ago the status of the chiropractor in this State was judicially defined. In May, 1914, one Leo E. Ellis, a chiropractor and a graduate of the Davenport University of Chiropractics, was charged with the crime of practicing medicine without a license. Mr. Ellis treated a woman by examining her ankle. He pronounced the arch as having fallen, massaged the foot and advised a different shoe. He manipulated the patient's spine which, speaking as a spinologist, he pronounced out of alignment in several places. He said he could restore it but it would probably not stay the first time. He gave the opinion that the nerves leading to the ankle might be impinged so as to cut off the circulation. He was of course convicted. By the unanimous Appellate Division of the Second Department the decision was thus upheld:

'Appellant's office, sign, his circular and professional card, as well as his own frank admissions as a witness, all shows that he holds himself out as able to diagnose, treat and prescribe for pain, injury and disease. Rubbing and pressure on the human joints are old therapeutic agents. When accompanied by such attempts at diagnosis as the statement that a patient's pains in the ankle were from the spine having come out of alignment through misplaced vertebrae, appellant's acts come within the statutory definition of the practice of medicine.'

Every man in the State of New York who has done what Ellis did has been guilty of the same crime.

In November, 1920, a chiropractor who maintained an office in one of the leading hotels of New York City treated an eight-year-old girl who was suffering from pericarditis and pleuritis for a period of ten days. While under his treatment the child died. In his own handwriting he made out a death certificate and delivered it to the undertaker. The certificate was, of course, refused by the Board of Health and the case turned over to the Medical Examiner's office.

The child had been previously treated in a hospital in this city from which, upon the recommendation of the chiropractor, the parents removed her and undertook his chiropractic treatment. The chiropractor took the child off the careful hospital diet and gave her apples to eat. The child died within ten days after this chiropractor started with his treatment. He was fined upon conviction in the sum of two hundred and fifty dollars or thirty days in prison. He paid the fine.

In May, 1921, a chiropractor having an office in this city, who engaged during the daytime as a clerk in a baggage room of a local railroad depot, was found guilty of practicing medicine without a license and fined fifty dollars. Whether or not he is still engaged in smashing baggage by day and spines by night we have not been informed.

Perhaps one of the most revealing cases was that tried in the Supreme Court of Kings County before Mr. Justice William Hagarty and a jury on April 8, 1924. The culprit chiropractor in this case was Ernest G. Meyer, a Palmer School graduate. Meyer had treated a six-year-old girl suffering with diphtheria, by adjusting the sixth cervical and fourth and eleventh dorsal vertebrae. The child died. A culture of the throat of the deceased showed the presence of Klebs-Löffler bacilli. Investigation by the health authorities disclosed that there were three other small children in the family who had been in contact with the deceased, one of whom had been sleeping with her while Meyer, the chiropractor, was in attendance. Meyer was indicted for the crime of manslaughter and was convicted by a jury of his peers.

One of the witnesses called in Meyer's defense was James G. Greggerson, a national lecturer for the Universal Chiropractic Association. Two of his answers on cross-examination should be enough to explode the chiropractic fallacy and its dangerous charlatanism once and for all time. The most simple credulity should not survive these answers:

"Q Mr. Greggerson, of course, it is not material in your estimation of this situation that Mr. Meyer did not know what the trouble with the child was, is it? A No, sir.

"G And yet in the face of the fact that Mr. Meyer said he didn't know and never knew until after the death of the child that the child had

diphtheria, you still say that your answer does not consider that of any moment? A Yes, sir"

How chiropractors treat diphtheria patients was revealed by the direct examination of Meyer himself

Q What did you observe and what did you do when you were called there? A I observed that the child was in a sick condition and I made a digital examination of the spine

Q What did that examination of the spine disclose to you? A It disclosed that the sixth cervical vertebra, the fourth dorsal vertebra and the eleventh dorsal vertebra were out of alignment causing pressure

Q After you made that examination, what did you do? A I directed the mother to prepare the child for adjustment, put the child on the bench—the chiropractic adjusting bench—and proceeded to adjust the misaligned segments into normal position"

And on cross-examination, this

Q Did you know that the child had diphtheria? A I didn't recognize it as diphtheria

Q And you never knew at any time during your treatment of the child that it had diphtheria? A No

Q And your system didn't indicate to you that it had diphtheria, did it? A I will say no

Q Mr Meyer, do you realize that one of the primary and absolutely necessary essentials to the cure of an ailment is the correct determination of what the ailment is? A No

Q So that you do not need to know what the trouble is in order to cure it? A We have the symptoms to go by

Q Will you answer that question specifically? A No"

If these things do not sufficiently expose the preposterously fraudulent chiropractic claims or reveal how great a menace to life and to limb is the practice of their quackery, turn to the textbook published by the Palmer School of Chiropractic, edited by the son of the founder of that school in 1921. Here is set down the proper and approved chiropractic practice according to the teachings of the founder of the cult. Were not this subject less vital to the public health, were not the lives of men, women and children constantly endangered by the chiropractic impositions, real amusement might be derived from the following directions of the Palmer book as to how the disciples of that school should treat their patients. It is all delightfully simple

"For barber's itch Adjust fifth dorsal

"For cataract of the eye Stand on the right side and adjust the sixth dorsal towards the left shoulder

"For chicken pox Adjust the fifth cervical. I have always been successful in relieving either chicken pox or smallpox by one adjustment.

"Consumption, a wasting disease of the lungs or bowels Adjust accordingly

"Diphtheria Adjust fifth dorsal for any of these throat affections, standing on the right side and throwing the vertebrae in the direction of the left shoulder

"Insanity Adjust atlas or third cervical

"Pneumonia Pneumonia should be relieved by one adjustment in the upper dorsal region

"Typhoid Fever Adjust the sixth dorsal and no other

"Typhus Adjust sixth dorsal"

Now comes Mr Esmond with his Assembly bill introduced January 12, 1926 (No 151, Int 153), sanctioning the practice of chiropractic in this State. After the passage of the bill, all those who would treat insanity by adjusting "the third cervical" or typhus by adjusting "the sixth dorsal" will be required to take certain examinations, but in the meantime all the present practitioners of chiropractic are to receive licenses (at ten dollars per license) provided they fall within one of the three following categories

(a) Graduates after a resident course of three years in a school teaching chiropractic who, during a period of *one year* immediately preceding the passage of the law, have been actually engaged in the practice of chiropractic in this State

(b) Graduates after a resident course of two years in such a school who, during the *last three years* immediately preceding the passage of the law have been actually engaged in the practice of chiropractic in this State

(c) Graduates after a resident course of one year in such a school who, during the last eight years immediately preceding the passage of the law, have been actually so engaged in chiropractic practice

One year in a chiropractic school under this proposed law means a period of "not less than six months"

This bill, if it becomes a law, will represent a new departure in the public policy of this State. For the first time law-breaking is to be rewarded. Not only is it to be rewarded, but the longer it has been engaged in, the greater the reward. The longer one has been concerned in trampling down the public health law, the longer he has pretended to treat and cure disease by spine manipulation the more entitled he be-

comes to the favorable consideration of the licensing authorities. The longer the period of his law-breaking, the less rigid are his educational requirements. Under this bill all those who have been for eight years following in the footsteps of chiropractor Meyer, of Brooklyn, provided they have been more alert than was Meyer in evading jail—all the Meyerites (of eight years' standing) who have kept out of the penitentiary, but who have done six months in a chiropractic school and have been graduated therefrom, are to be rewarded by this State with a license to 'practice chiropractic.' All those who have been smashing trunks by day and spines by night, provided they have done so long enough and have otherwise met the requirements of this bill, will receive a license to use "the degree of D C" or "Doctor of Chiropractic."

How many who have been knowingly and deliberately engaged in violating the Public Health Law of this State the proposed law would license it is impossible to determine. It is, however, certain that these amnesty provisions would license chiropractors of this state now unlawfully practicing their so-called "profession."

But this is not all. A duly licensed practitioner of chiropractic who has complied with the provisions of the bill "shall be subject to all the disabilities, limitations and restrictions and entitled to all the civil rights, privileges and immunities imposed upon and granted to all professional persons by the Civil Practice Act and the Judiciary Law."

Under Section 31 of the Judiciary Law, in criminal actions and in certain special proceedings "in which the soundness of mind of a person is in issue, the court may appoint not more than three disinterested, competent physicians to examine such person as to his soundness of mind at the time of the examination." If the Esmond bill becomes a law, a judge could lawfully appoint from one to three chiropractors to determine the question of a person's sanity. How insanity is treated under the Palmer method we have already seen. It is done in this way "Adjust atlas or third cervical." How the difficult and intricate question of insanity is to be determined is a problem in which the chiropractor is not interested, because it is one of the tenets of his doctrine that diagnosis is of no consequence or importance. The chiropractor scorns diagnosis. In the Meyer case the expert chiropractic witness Greggerson testified that in diphtheria it was not necessary "to know what the trouble with the child was." No doubt this chiropractic

doctrine extends to insanity as well. Thus, if the proposed bill becomes a law three chiropractors might occasion the commitment of a person to an insane asylum without knowing or considering it necessary to know that he was insane.

Nor is this all. Under the proposed bill "within twenty days after the first one hundred licenses have been issued under this act, the regents shall appoint one of such licensees as an additional member of the State Board of Medical Examiners. Such appointee shall not be a medical doctor."

Into the council, therefore, of the Board of Medical Examiners, charged with the onerous and responsible trust of determining the fitness and qualification of those who are to treat the sick and to safeguard the public health, there is to be thrust a chiropractor! Into the counsels of this body there is to be injected the Palmer doctrine and that of his followers, dupes and imitators. In the deliberations of this Board one may sit who believes that typhus is properly treated by adjusting the "sixth dorsal", that for diphtheria "adjust fifth dorsal", and who is ignorant of or scorns the germ theory and all other scientific knowledge.

But what of the public health? What of contagious disease? What of the dangers of a plague? What of smallpox, typhoid fever and diphtheria? What of the safeguards against those things which science has built up, safeguards which have stood the test of the most exacting scientific scrutiny and which have protected and saved the lives of countless thousands? Shall we abandon all these safeguards merely to enable baggage smashers to increase their revenue? Shall we turn loose an ignorant army to prey upon the public health? Shall we permit the State to license those who would treat diphtheria by manipulation of the spine? Shall the people of this State be laid upon the "chiropractic adjusting table" as chiropractor Meyer laid his patient? Meyer was less fortunate than many of his fellow chiropractors, he did not escape the clutches of the law. The vigilant district attorney of Kings County brought him to justice. Because of his criminal ignorance and folly he was convicted for the manslaughter of his patient, but this did not restore the little girl to her weeping parents.

It is time to strike at "Meyerism." The bill should be defeated! It must be defeated. With the aid of an intelligent and an aroused understanding it will be defeated.

State Department of Health

Milk-Borne Poliomyelitis

Dr Edward S Godfrey, Jr, Director of the Division of Communicable Diseases, spent some time recently in a personal investigation of an epidemic of poliomyelitis in the City of Cortland. As a result of his studies Dr Godfrey feels sure that the disease was milk-borne, the first definite outbreak of this character ever described.

On December 7, 1925, a boy sixteen years old, who was working on the dairy farm where the milk concerned was produced, became ill with fever, diarrhea, headache and pain in the back. In spite of his illness he continued at work, milking eight or ten of the twenty cows on the farm. He continued at work for the next three days although he noticed his hands were becoming progressively weaker and he suffered with pain and tenderness in his left arm. On December 11th he was definitely paralyzed in his left upper extremity and his right deltoid muscle but did milk three cows with his right hand before his condition was noticed. From that time he was isolated. A short time previous to the onset of his illness the boy had attended a motion picture theatre. The woman who sold tickets had a child at home suffering with poliomyelitis.

On December 14th, seven days after the onset of the first case, another case developed and others occurred as follows: December 16th, two cases, 18th, two, 19th, one, 25th, three (one of which is a doubtful case). The cases varied in age from 15 months to 22 years, were scattered over the city and investigation did not show contact between them or the original case in any way.

The only point in common was that all but two of the subsequent cases drank milk produced on the farm where the first case was employed. The exceptions were a boy of 19, whose mother worked in a restaurant which purchased daily thirty-five quarts of this milk, and the doubtful case, which did not use the milk.

The dairy from which the milk came sold 215 quarts of milk unpasteurized in the City of Cortland, whose daily supply is about 5,700 quarts.

Diphtheria Toxin-Antitoxin Mixture—Method of Preparation and Testing

The Division of Laboratories and Research, by special request, has prepared the following:

"The following procedures are used in the preparation of diphtheria toxin-antitoxin mixture (O L mixture) at present distributed by the state laboratory in Albany.

The toxin used in the mixture is the phenolized filtrate of a seven-day broth culture of the stan-

dard strain of *B. diphtheria*, which has stood in the cold room for at least one year. This stabilized toxin is restandardized carefully against an antitoxin of known titer to determine its L dose (the least amount of toxin which when combined with one unit of standard antitoxin will cause the death of a guinea pig weighing two hundred and fifty grams within ninety-six hours). The toxin and the antitoxin are then combined with sterile precautions in such proportions as to give a slightly toxic mixture when diluted with physiological salt solution so that 1 cc contains 0.1 of an L dose of the toxin. At present each cc of mixture represents a combination of 0.014 to 0.017 cc of toxin and about 0.00008 cc of antitoxin, diluted with salt solution containing 0.4% of phenol.

The diluted mixture is filtered and careful tests for sterility, toxicity and potency are made. In the final toxicity tests several guinea pigs are injected, some with 5 cc (five times the human dose), others with 1 cc. No mixture is used, 5 cc of which causes the death of a guinea pig in less than ninety-six hours. Guinea pigs receiving this dose should die in from four to six or eight days, although an occasional animal may live longer. The guinea pigs receiving 1 cc develop paralysis in about three weeks, but do not usually die. Intracutaneous tests, similar to the Schick test, are performed on these animals for the purpose of obtaining some indication of the immunizing value of the mixture. Three weeks after injection of the mixture, the guinea pigs receive their first test. If the reaction induced indicates that insufficient antitoxin has developed, the test is repeated a second or, if necessary, even a third time, the tests being made a week apart. The number of tests required, one, two or three, is the so-called "immunity index."

"The finished product is bottled for distribution, special precautions being taken to insure sterility. The material in the final containers is tested for sterility in two kinds of culture medium, and 3 cc are injected into a guinea pig as a final control of the harmlessness of the mixture for human use.

"In the mixture now distributed the toxin and antitoxin are diluted approximately 1:70 with salt solution. One cubic centimeter contains, therefore, an exceedingly small amount of protein. Since the guinea pigs receiving five times the human dose must live more than ninety-six hours, the time of death on which the minimal fatal dose (M F D) is based, one human dose of mixture probably contains somewhat less than one-fifth of an M F D of free toxin."

NEWS NOTES

RESOLUTION ON TOXIN-ANTITOXIN

The following resolution was passed by the Executive Committee of the Council on January 14, 1926

Resolved, That the President shall appoint a committee of ten, which shall include a member from the State Department of Health, and one from the State Charities Aid Association, the Director of the Academy of Medicine, the President of the New York State Homeopathic Society, the Chairman of the Committee on Public Health and Medical Education of the State Society, the Chairman of the Committee on Medical Economics of the State Society the President of the Medical Society of the State of New York, and three other members to be chosen from the Medical Society of the State of New York, for the purpose of formulating a plan of campaign

to make diphtheria toxin-antitoxin available to every child in the state, and of devising a method by which the medical profession may cooperate with the State Department of Health and other agencies in the universal application of the means of immunization against diphtheria and that every practitioner of medicine who wishes may have a part in its administration

The President appointed the following committee Dr Matthias Nicoll, Albany, Mr Homer Folks, New York, Dr Linsly R Williams, New York, Dr George F Raynor, New York, Dr Charles A Gordon, Brooklyn, Dr W Warren Britt, Tonawanda, Dr Frederick E Sondern, New York, Dr Herman G Weiskotten, Syracuse, Dr William H Ross, Brentwood, Dr Nathan B Van Eften, New York

TESTIMONIAL TO ROCHESTER'S HEALTH OFFICER

The program of a dinner of Dr George W Goler, given on December 8, 1925, begins as follows

"This dinner is offered by the Medical Society of the County of Monroe as a testimonial to the good citizenship of George Washington Goler, M D, who has courageously and high-mindedly for twenty-seven years performed the high functions of his office as health officer of the city of Rochester"

Dr Floyd Winslow gave a humorous and witty history of Dr Goler and showed photographic slides from the time he was one year old to the time when he won the war as a Colonel He thought that the whole dinner was a conspiracy against truth He said that Goler nearly arrested him once for failing to register a birth and that he was the only man in the audience who would get up and show the audience what kind of a man Goler was after all

Dr E T Wentworth delivered an address on the chiropractic representing himself as broadcasting from a certain chiropractic school His speech over the radio was very humorous and much appreciated

The program of the after-dinner speaking was as follows

Alvah Strong Miller, President, Medical Society of the County of Monroe,

Dr Rush Rhees, Toastmaster, President of the University of Rochester,

Clarence D Van Zandt, Mayor of the City of Rochester,

George Eastman, Citizen of Rochester,

Augustus Wadsworth, New York State Department of Health,

George Hoyt Whipple, Dean of the University of Rochester Medical School,

William D Johnson, Physician and Surgeon, Batavia,

George Washington Goler, Health Officer of the City of Rochester

Dr Goler is well known to physicians throughout New York State, and especially to its nine hundred health officers Speaking of Dr Goler's work, Dr William D Johnson, of Batavia, drew attention to the fact that partly because of his own lack of interest in public health matters that he knew little about Dr Goler's work He had, however come to know that the country had two outstanding health officers He knew one to be Dr Goler, but had forgotten the name of the other Dr Johnson paid a rich tribute to the spirit of preventive medicine and whole-heartily endorsed the idea of physicians devoting their whole time to community welfare in matters of health

Dr Goler in his response said "I was called with Dr Mott Moore, the man who gave my life its inspiration, to see a family in which there was diphtheria Twelve children were sitting around the table, ten of them had sore throats Dr Moore said in three weeks they will all be dead. Dr Moore was right That was in the days before diphtheria anti-toxin"

LIST OF EDUCATIONAL ARTICLES USED IN THE CAMPAIGN AGAINST THE COMMON COLD CONDUCTED BY THE PUBLIC HEALTH COMMITTEE OF THE ROCHESTER CHAMBER OF COMMERCE

No	Date of Issue	Title	Author
1	Sunday, October 18th & Mon, Oct 19th	"The Common Cold"	Geo W Goler, M D Health Officer
2	Sat P M Oct 24th	"Building Up Resistance to Colds"	Wm Sharp McCanne, M D Prof of Medicine University of Roch Medical College
3	Sun, Nov 1, and Mon P M, Nov 2nd	"The Relation of Fresh Air, Humidity & Heat to Colds"	Wm A Sawyer, M D Med Dir Eastman Kodak Co & Vice Pres of the Pub Health Committee of the Chamber
4	Sat, Nov 7 & Sun, Nov 8	"Colds in Children"	Albert D Kaiser, M D Pres of the T B & Public Health Association
5	Sat, Nov 14 & Sun, Nov 15	Detecting the Oncoming Cold"	John J Lloyd, M D Former Med Director of Mon Co T B San
6	Sun, Nov 22 & Mon, Nov 23	"Colds in the Schools"	Herman J Norton, Dir of Health Educ Roch Dept of Public Instruction
7	Sun, Nov 29 & Mon, Nov 30	"Catching a Cold"	Stanhope Bayne-Jones, M D Prof of Bacteriology, U of Roch Medical School
8	Sat, Dec 5 & Sun, Dec 6	"The Relation of Clothes to Colds"	Marion Craig Potter, M D
9	Sun, Dec 13 & Mon, Dec 14	The Physiology of Colds"	Wallace Osgood Fenn, M D Prof of Physiology, Univ of Roch Medical School
10	Sat, Dec 19 & Sun, Dec 20	The Relation of Foods to Colds	John R Murlin, Ph D Dir Dept of Vital Economics, Univ of Roch chrman Public Health Com

BRONX COUNTY MEDICAL SOCIETY

The Annual Meeting of the Bronx County Medical Society, held at Concourse Plaza, on December 16, 1925, was called to order at 9 P M, the President, Dr Jacobs, in the Chair

The following Officers, Censors and Delegates were elected for the year 1926

President, Edward R Cuniffe, 1st vice-president, Louis A Friedman, 2nd vice-president, Samuel Gitlow, secretary, I J Landsman, corresponding secretary, Samuel F Weitzner, treasurer J Adlai Keller, Censors William Klein, Louis Sheinman, Delegates to State Society Harry Aranow, Edward R Cuniffe, Edward C Podvin, Norman Roth, Alternates Moses H Krakow, Louis Nagorsky, Samuel Roscnweig Benjamin Sherwin

The Secretary read a letter from Dr Kopetzky, President of The Medical Society of the County of New York, enclosing minutes of the Con-

ference on the Nursing Situation by Committees Representing the Medical Societies of the Greater City of New York, held on December 9th, and also a copy of the Resolutions passed by the New York County Society It was moved and carried that the Bronx County Medical Society adopt similar Resolutions

The rest of the evening was devoted to the question of erecting a building suitable for the needs of the Bronx County Medical Society After Dr Cuniffe, Chairman of the Building Committee, submitted the Report of the Committee, and the members of the Society pledged between forty and fifty thousand dollars toward this Fund The ambition of the Society is to erect an Academy of Medicine in the northern part of the Bronx, which shall be a centre to the adjacent counties and cities north of the Bronx

MEDICAL SOCIETY OF THE COUNTY OF MONTGOMERY

The annual meeting of the Medical Society of the County of Montgomery was held in Amsterdam, Thursday, December 10, 1925, at the Y M C A building. The meeting was called to order at three o'clock by the President, Dr James S Walton.

The afternoon session was taken up by Dr Samuel Tirman, of Brooklyn, with a clinic on "Methods of Physical Diagnosis." Forty cases of heart disease were presented by various physicians coming from different sections of the county. The physicians present were able to listen to the heart sounds by using the multiple stethoscope.

The evening session was called to order at 8:15 and the following officers were elected for the ensuing year:

President, E Harrison Ormsby, Vice President, Clayton Fox, Secretary, William R Pierce, Treasurer, Seymour Homrighouse, Censors, Dr William H Bing, Dr E C LaPorte, Dr Charles Stover, Delegate, House of Delegates, Dr Horace M Hicks.

A resolution was adopted endorsing the movement for the national endowment fund for a physicians' home, and another approving the State Department of Health's plan to have all children protected against diphtheria by toxin-anti-toxin.

Following the business meeting, Dr Richard Morgan, associate physician at Mount McGregor, read a paper on "The Care of Tuberculosis by the General Practitioner." Dr Samuel Tirman gave a paper with blackboard demonstrations on the new conceptions of cardiology. There being no further business, the meeting adjourned.

THE DUTCHESS-PUTNAM MEDICAL SOCIETY

The annual meeting of the Dutchess-Putnam Medical Society was held at the Hudson River State Hospital, Poughkeepsie, on January 13, 1926. The following officers were elected for the ensuing year:

President, F B Weaver, Hyde Park, Vice-President, J N Boyce, Poughkeepsie, Secretary-Treasurer, H P Carpenter, Poughkeepsie, Associate Secretary, Aaron Sobel, Poughkeepsie, Delegate for Three Years, W A Krieger, Poughkeepsie, Alternate for Three Years, R H Breed, Wappingers Falls, Censors, A L Peckham, J W Poucher, J Coborn.

Dr W G Thorne of Poughkeepsie was

elected to membership. Dr C J Patterson of Poughkeepsie was received on transfer from Rensselaer County.

SCIENTIFIC SESSION

"Recent Progress in the Treatment of Cataract of Interest to the General Practitioner," illustrated with lantern slides, Isaac Hartshorne, M D, New York City.

"Birth Control" by James F Cooper, M D, New York City.

A dinner was served at the Hudson River State Hospital at 6 P M. About fifty were in attendance.

MEDICAL SOCIETY OF THE COUNTY OF JEFFERSON

The regular meeting of the Medical Society of the County of Jefferson was held on January 14, 1926, Dr P E Thornhill as Secretary. He acted in the absence of Dr W Atkinson who was abroad visiting clinics in Europe.

Dr M Lee Smith and Dr George F Bock were unanimously elected to membership.

The amalgamation of the Medical Society of the City of Watertown and the Medical Society of the County of Jefferson was completed. This amalgamation was considered advisable owing to the fact that the County Society only met twice a year and the interest in it was on the wane, whereas the City Society, though small, held monthly meetings and was active. The consolidation of these societies would make it possible to have a much more active County So-

cietly and meetings every month with the exception of July and August.

The program committee reported that they had secured an out-of-town speaker for every second meeting this year, the alternate meetings to be addressed by members of the Society. The address at the December meeting was by Dr Russel L Cecil, New York, on "Pneumonia."

Arrangements have been made for a course of six lectures on pediatrics to take place this coming spring. Jefferson and St. Lawrence Counties are also arranging a joint program similar to the joint program of Obstetrics last spring. These lectures are of great benefit to the membership and activity of the Society. The attendance at meetings has been greatly increased by them.

THE DAILY PRESS

Lay Health Organizations

Who is responsible for the health conditions of a community? The Department of Health is a correct answer for those who believe in paternalism in government. The family doctor is the answer of those who believe in individualism and American independence of action.

Both answers are correct. The principles of both paternalism and independence of action must be applied to every public health problem.

The principle of paternalism is not opposed to that of individualism to the extent that might at first appear. Paternalism is the exercise of external authority or force which is none the less real because it is benevolent. The influence of style, custom, and habit on individuals is as compelling as that of the police, and the restraints of polite society are more effectual than statute laws. The American people will act in accordance with the prevailing custom or what they think the other fellow is doing, and that is often directed by the funny pages of the daily press.

The question arises: Who are the leaders in establishing health customs? Departments of health set the official standards, lay organizations advertise them and "sell" them to the public, and family doctors carry out the details of their application to individuals. This is the ideal scheme of action in public health activities.

The three-fold division of labor is still somewhat idealistic and visionary. The standards set by Departments of health are probably permanent, although they are subject to minor changes wherever new hygienic discoveries are made.

The advertising and selling plans of the lay organizations are still incomplete in so far as the organizations fail to cooperate with the family doctors or to secure their support. The direct activities of lay health organizations—lectures, exhibits, printed matter, and nursing—reach only a small proportion of people, while doctors reach practically all the people. A movement by lay organizations to secure the cooperation of family doctors would be a great item of advance in public health work.

These reflections are inspired by an address by Dr. Louis I. Harris, Commissioner of Health of New York City, reported in the *New York Herald-Tribune* of January 17. Speaking before the American Social Hygiene Association, the Commissioner said that public officials are looking more and more to private welfare

and health organizations to work for better health and social conditions in the city.

The concrete application of the principle expressed by the Commissioner would seem to be that the standards set by the Department of Health should be advertised and sold to the public by lay organizations, and that family doctors, or their official organizations, should also be enlisted in the sale of good health.

Beauty Doctoring

Beauty doctoring is seemingly as popular as ever, although the methods as well as the results have been vastly improved in recent years. It is not easy to find a really homely looking girl now-a-days, as the members of the Beauty Shop Owners Convention found, according to the *New York Herald-Tribune* of January sixth. The girl chosen for her lack of beauty was subjected to a half day's manipulations of the beauty specialists, who subjected her to "brilliantine, muscle oil, tar tonic, astringent lotion, erasator, scalp tone, calmine lotion, tissue cream, whiting cream, astringent cream, lemon cream, lettuce cream, cucumber cream, spinach cream, jassmin cream, nail bleach, cuticle remover, face powder, rouge naturelle, almond cream, skin food, almond meal, a clay pack, wrinkle cream, icitone lotion, tincture of jaborandi, tincture of mullein, tincture of capsicum, bluing, skin tightener, mani rosa oil, and pluck her eyebrows."

The director of the transformation is reported to have said: "It is wonderful. Now you can get a beau and maybe a husband." "Beau, nothing!" replied the glorified girl, "come around to the church a week from today and see me married to my fellow. We became engaged long before I became beautiful."

After reading this account we had visions of writing an easy column on the methods and costs of beauty made to order as revealed in the pseudo-scientific advertisements in the women's magazines, but we were disillusioned. The garish advertisements of a dozen years ago have almost completely disappeared from the better class of monthly magazines, and we had difficulty in finding a sufficient number of the old-time beauty advertisements to serve as illustrations. One of the most prominent magazines had only two bizarre advertisements. A hair dye was advertised with a picture of a beautiful white-haired woman looking daggers at a black-haired matron to whom her young husband was attracted—presumably by the glossy locks. The other was a half column

advertisement of "kissproof lip sticks" (This brand should be recommended to a prominent dentist whom we heard complaining about the annoyance of getting his lady patients' red dye sneared over his hands and white coat)

What kind of advertisements are taking the place of the beauty appeals of a decade ago? The appeal is still very properly there, but it is on a more rational basis. The prominent journal to which we have referred carried major advertisements which had health or beauty appeals on the following subjects

Soap	5 advertisements
Foods	11 advertisements
Cold Cream	7 advertisements
Tooth Paste	3 advertisements
Hair Restorers	2 advertisements
Toilet Articles	5 advertisements

The highest class magazines still carry a very few of the old time crude beauty advertisements in abbreviated form in inconspicuous positions. But the beauty advertisements appear in greater number and size in the monthlies devoted to fashions and gushy novels. There the ladies are urged to buy their hair tonics and destroyers, luster preservers and restorers, skin foods and cleansers, fat producers and reducers, sleep inducers and vigor producers—in fact anything you want.

But the biggest offenders are found among a class of magazines whose specialty is to abuse the medical profession, and whose greatest assets are false names implying the promotion of health and vigor. In these periodicals the old time lurid promises are blazoned forth, and are presumably financially successful. Still, physicians need not be pessimistic. These journals flourish if an exceedingly small proportion of the people patronize them and their advertisers. The optimistic fact remains that the periodicals which have the big circulations and reach the majority of the homes of the nation now seldom print the misleading advertisements to which doctors object.

Air-Borne Pneumonia

The New York Sun, January 14th, contains an article on the analyses of samples of air taken from the capitol in Washington. The article says:

'An epidemic of pneumonia in Washington, marked by a sharply rising death rate, has caused officials of the Federal and city governments to order inspection of ventilation systems in all public places. In addition, government scientists are making laboratory tests of

air in the Capitol and other government buildings. Work of this kind was first undertaken two years ago when there were a number of deaths among senators. As a result the ventilating system of the Capitol was enlarged and improved, and the new tests and germ count will show the result."

"A special inspection of the ventilating systems in all theaters, halls, and department stores has been ordered by the local health authorities. Air samples are not being taken in the theaters and other places which have already approved ventilating systems. It is the opinion of city officers that the systems are ample, if they are working properly."

This is excellent propaganda so far as it goes. It is efficient in calling attention to ventilation, and the scientific methods of measuring the constituents of air and of providing air that conforms to a high standard of comfort and decency. But the relation of ventilation to pneumonia and other air-borne diseases is not explained in the articles.

The importance of "fresh" air is stressed in popular writings, the greater importance of disease germs in foul air is less emphasized, while the danger created by the presence of a person spreading pneumonia germs is scarcely mentioned at all. It is true that the danger from coughs and sneezes is mentioned in schools and health lectures, but the people generally are still in ignorance of the ordinary chain of events that happen when air borne infections occurs.

The impression given by articles on ventilation is that fresh air is a panacea and a universal prevention for all kinds of respiratory diseases. But fresh air is only one element in their prevention, and not the greatest. The people need to be taught that respiratory diseases are contagious and are spread by persons who are affected with the diseases. The three points to be emphasized are the presence of disease germs in the nose and throat, their expulsion in coughs, sneezes, and talking, and their carriage to others by "droplet infections." The weakness of this line of instruction is the inability of bacteriologists to detect or identify many of the common germs that produce respiratory diseases. But there is overwhelming evidence that acute respiratory disease are contagious, and that the sick have caught their diseases from previous patients.

Let us have propaganda for ventilation and fresh air. Let us also have popular instruction regarding the most common mode of transmission of acute respiratory diseases.

DEATHS

- BROMLEY, LOVINE A, Granville, University of Vermont, 1882, Member State Society Died December 2, 1925
- BRONSON, EDWARD BENNET, New York City, College of Physicians and Surgeons of New York, 1869, Member State Society, New York Academy of Medicine, Alumni Bellevue Hospital, Consulting Physician City and Babies' Hospitals Died November 18, 1925
- CARSON, JAMES CARLTON, Syracuse, Bellevue Medical College, 1870, American Association for Study of Feeble Minded, Syracuse Academy of Medicine, Member State Society Died January 1, 1926
- DRAPER, WILLIAM KINNICUTT, New York City, College of Physicians and Surgeons of New York, 1888, Fellow American Medical Association, National Tuberculosis Association, New York Academy of Medicine, Member State Society, Visiting Physician Bellevue Hospital, Consulting Physician New York Orthopedic Hospital Died January 5, 1926
- EBERLE, EDWARD, Brooklyn, Kentucky School of Medicine, 1898, Member State Society, Assistant Surgeon Brooklyn Eye & Ear Hospital Died December 18, 1925
- ELLIOTT, EDWARD ROSS, Montgomery, New York University, 1874, Member State Society Died January 7, 1926
- LAW, JAMES, New York City, New York University, 1891, Fellow American Medical Association, New York Academy of Medicine, Member State Society, Physician Harlem Dispensary Died December 26, 1925
- LEE, JOHN MALLORY, Rochester, University of Michigan, 1878, Fellow American Medical Association, American Radium Society, Member State Society, Consulting Surgeon Gowanda State Hospital Died January 11 1926
- MANDL, NICOL MARTIN, New York City, Vienna, 1891, Fellow American Medical Association, Member State Society, Attending Pediatrician Hospital Joint Diseases Died January 2, 1926
- MECCHELLA, GIOVANNI, Brooklyn, University of Naples, 1898, Member State Society Died November, 1925
- MYERS, THADDEUS HALSTED, New York City, College of Physicians and Surgeons of New York, 1885, Fellow American Medical Association, American Orthopedic Association, New York Academy of Medicine, Member State Society, Alumni Association St Luke's Hospital, Orthopedic Surgeon St Luke's, St John's, State Crippled & Deformed Children and New York Nursery and Childs Hospitals Died December 24, 1925
- PURDY, WILLIAM H, Mt Vernon, Bellevue Medical College, 1898, Fellow American Medical Association, Member and former Vice-President State Society, Chief Medical Staff Mt Vernon Hospital Died December 16, 1925
- RENN, PIUS, New York City, New York University, 1896, Fellow American Medical Association, Member State Society, Alumni Association Lenox Hill Hospital Died December 31, 1925
- SWIFT, GEORGE MONTAGUE, New York City, College of Physicians and Surgeons of New York, 1879, Fellow American Medical Association, New York Academy of Medicine, Member State Society, Alumni Associations Bellevue and Foundling Hospitals Died December 26, 1925
- THATCHER, HAINES C, West Danby, Hahnemann, Chicago, 1889, Member State Society Died January 18, 1926

BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

THE ART AND PRACTICE OF MEDICAL WRITING By GEORGE H. SIMMONS, M.D., Editor and General Manager Emeritus, American Medical Association, and MORRIS FISHBEIN, M.D., Editor, *The Journal of the American Medical Association*, Chicago American Medical Association Press, 1925

THE OLD TIME COUNTRY DOCTOR. A special article published in *The Journal of the American Medical Association* By WILLIAM ALLEN PUSEY American Medical Association Press, 1925

BOOK REVIEWS

MEDICAL CLINICS OF NORTH AMERICA Published every other month by the W. B. Saunders Co., Phila and London Per Clinic Year (6 issues) Cloth, \$16.00 net, paper, \$12.00 net

Volume 8, Number 5, March 1925 (Boston Number) The Boston number of the Medical Clinics of North America maintains the high standard of this publication. This issue is written by many of the eminent men of Boston well qualified by experience and training in special lines relating their experience and deductions drawn from their work in the various hospital clinics of that city.

The articles are written in a clear readable style and contain many points of value to medical men.

The articles on problems of diabetes, splenomegaly in children, and generalized enlargement of lymph nodes and spleen with chronic focal infection are particularly interesting. C. E. HAMILTON

Volume 8, Number 6, May, 1925 (Boston Number) The Medical Clinics of North America are always interesting as to a certain extent, and perhaps to a considerable extent, they represent the prevailing fashions in the region from which each number appears. At the same time they represent the prevailing interest of a portion of the country in a particular part of the human economy. As this particular number hails from Boston it is to be expected that a considerable part of the issue would be taken up with articles on the heart. Such is the case. All of the articles on heart problems contain information of value to all physicians dealing with the sick.

The number contains a very interesting article on urinalysis, which would make good reading for anyone, as it is pregnant with salient truths. Equally as interesting is the article on gout, as that disease is not commonly seen, and unless one is reminded of it occasionally, it is overlooked.

Gall bladder, peptic ulcer, arthritis, and endocrines, of course, come in for some review, and to end the issue Joslin outlines his method for the treatment of diabetic coma. All of these subjects are treated so as to bring out worthwhile problems of clinical medicine.

J. ARTHUR BUCHANAN

ORGANIC MEDICAMENTS AND THEIR PREPARATION By ERNEST FOURNEAU. Authorized translation by W. A. Silvester, M.Sc. Octavo of 262 pages, with 22 illustrations. Phila, P. Blakiston's Son & Co., 1925. Cloth, \$4.25.

This is a unique, interesting and valuable book to those interested in pharmacology and bed-rock details of therapy.

Dr. Fournneau is a master chemist and has condensed into two hundred and fifty pages the technical methods of producing most of the common synthetic drugs in use today. It is a most readable presentation of an ordinarily technical subject.

The author's familiarity with physiology and pharmacology has permitted many deductive applications of organic medicaments that should prove helpful.

M. F. DeL.

AIDS TO OBSTETRICS By SAMUEL NALL, B.A., M.B., Cantab. M.R.C.P., Lond. Revised by C. J. NEPEAN LOVGRIDGE, M.D., Vict., F.R.C.S., Eng., M.R.C.P., London. Ninth Edition. William Wood and Co., New York, 1925. Price, \$1.25.

This ninth edition of a popular little book is a remarkably well condensed, yet fairly complete "skeleton of essential facts." Though not arranged in the familiar question and answer form of the compend, it answers the same purpose. C. A. G.

A PRACTICE OF GYNÆCOLOGY By HENRY JELLET, M.D., F.R.C.P.I. Fifth Edition. Octavo of 744 pages with 417 illustrations and 15 colored plates. Philadelphia, Lea and Febiger, 1925. Cloth, \$8.50.

This splendid textbook is a credit to the author and the publisher. This edition has been very carefully revised, and contains the latest work of Novak on menstruation, and the transuterine pneumoperitoneum studies of Rubin and Peterson, although Jellett is skeptical as to the practical value of X-ray examination after inflation of the abdominal cavity. Sampson's recent epoch making work on implantation adenomata is included, and one of Sampson's beautiful color plates adorns the volume. Vaccine therapy and the story of uterine displacements is thoroughly covered. The book is distinctly up to the minute. C. A. G.

A MANUAL OF PHYSICAL DIAGNOSIS By AUSTIN FLINT, M.D., LL.D. Ninth Edition, revised by HENRY C. THACHER, M.S., M.D. 12mo of 320 pages, illustrated. Philadelphia, Lea and Febiger, 1925. Cloth, \$3.00.

In the preface, the author states that the manual is to fill "the demand of the student and of many graduates in medicine for simplicity, directness, exactness, and skill in dealing with the physical signs in health and disease." The book in a very meager way fills this demand.

Many important physical findings are omitted. Gower is not even mentioned, and the same applies to the abnormal physical findings in the eyes. A common physical finding in many lung and cardiac conditions, namely, clubbed fingers, is omitted. The nerve reflexes are not even mentioned. A method for taking blood pressure is not given. Such a subject is not considered.

The cardiac arrhythmias receive scant consideration. In fact, the two commonest receive a little over a page for their discussion. Under auricular fibrillation, it is stated that with exercise the mild cases may be detected as the irregularity is increased with the frequency. If a pulse in the beginning is completely irregular, it can not be made more than complete. If one did not know in advance how to recognize the arrhythmias clinically, little help would be derived from reading this section of the book.

The book is of value in its historic sense but should be more inclusive of such omissions as we have mentioned in order to fulfill its purpose of an up to date manual. J. ARTHUR BUCHANAN

DISEASES OF THE BRONCHI, LUNGS AND PLEURA By FREDERICK T. LORD, M.D. Second Edition, thoroughly revised, chapter on pulmonary tuberculosis. Octavo of 776 pages with 107 illustrations and 3 color plates. Lea and Febiger, Phila., 1925. Cloth, \$8.00.

The author considers all diseases of the bronchi, lungs, and pleura, whether the disease happens to be a common or a rare one. He possesses the happy faculty of considering important diseases in a complete way, while the unimportant ones receive but limited consideration. There is also an extensive bibliography throughout the book.

The therapeutic measures are very simple in most instances, and the many drugs for lung therapy that are so widely advertised today are not mentioned.

The most unusual statement in the book is that the use of all remedies for the desensitization of persons with asthma have no real value, and are of little use. This is a wide departure from current practice in many quarters where patients are being desensitized against all sorts of agents.

The author presents a book for value as a reference book and a therapeutic guide for diseases of the chest, excluding the heart. J. ARTHUR BUCHANAN

OBSERVATIONS ON RENAL AND URETERAL CALCULI

By EDWARD F KILBANE, M D

NEW YORK CITY

It is the purpose of this paper to consider only those cases where the presence of a stone either in the ureter or in the kidney pelvis is the predominating lesion. The symptomatology is practically the same in either case, and the treatment will differ in detail only.

Some degree of infection is present with every calculus, and if the calculus remains for some time, this varying with different individuals, the infection may progress to the point where it is the predominating lesion, even to the point of complete destruction of a kidney or the presence of a generalized sepsis. That type of case constitutes a distinct clinical entity quite without the scope of the present paper. Fig 1, II, and III.

Fig 1

Fig 2—Roentgenogram of type of stone illustrated in Fig 1

One of the most frequent questions asked by patients who have calculi, refers to the cause of stone formation, and it is one of the most natural, for knowing the cause, one is in a position to so shape his mode of living that the chance of recurrence is removed or reduced to a minimum.

Unfortunately, however, of the etiology of stone formation we know but little. There are indeed but few subjects on which we have so little accurate knowledge, and probably on none is there more misinformation.

We know that under normal circumstances the urine maintains in solution in crystal form, urates, phosphates, oxalates and other similar substances. Further we know that under some circumstances, which we must consider abnormal circumstances, these crystals cease to maintain their individual isolation in passing through the urinary tract—some mechanism causing them to

Fig 3—Pyelogram of same kidney as Fig 2 showing extent to which the destruction of the kidney parenchyma has progressed

be precipitated in a manner to form hard fused concretions, or in other words stones

In the excretion of many substances by the kidney, urea, uric acid, creatinin, sugar and chlorides, the concentration of these substances in the blood seems to be the stimulus and controlling factor to the kidney for their excretion

It might seem, and it has been quite generally assumed, that there is a high incidence of lithiasis in such diseases as are characterized by increased blood concentration of some of these salts or in those conditions characterized by a visible increase in the crystalline content of the urine, but little statistical evidence is offered to support these contentions. The three commonest conditions associated with an excessive crystalline content in the urine, oxaluria, phosphaturia and gout are found far more frequently without calculous formations than with it, which would tend to prove that increased crystalline content is not in itself the important factor. Also it is conceivable that normally there is a protective mechanism at work to maintain crystals in solution, that this mechanism may be quantitative as well as qualitative and that at times excessive secretion of crystalloid materials may reach such proportions that the normal mechanism is lost through the exhaustion of its protective colloids to the end that the excess of crystalloid material precipitates into formed concretions

Geographic distribution, race, heredity, age, sex, diet (including water), and trauma seem to offer but little constructive suggestions relating to the formation of concretions. If factors at all they are probably of secondary importance, contribu-

tatory possibly only in the presence of more definitely causative factors. Further there is little conclusive evidence that anatomical factors or urinary stasis can imitate the stone forming process, but their frequent association with calculus makes it seem likely that the stone forming mechanism may work to better advantage when such conditions exist. The problem of urinary calculus formation is apparently one of chemical precipitation. Differences of reaction as determined by the hydrogen ion concentration and quantitative and qualitative changes in the colloidal materials, mucin, pigments, albumen and nuclealbumen in the urine influence the nature of urinary sediments both chemically and physically, and the microscopic and gross features of calculi seem to show that an abnormal variation of these factors is at work in the formation of calculi. The chemical evidence seems to point to a local mechanism at work in the kidney or bladder. The frequent occurrence of foci of infection in patients with calculi would seem to point to more than a casual relationship. Also there is almost constantly found infection of the kidney or bladder in association with stone. But it is not possible at the present time to accept in its entirety the idea of a specific stone forming infection, despite the definite views to that end that have been expressed. However, it is probable that infection comes nearer to explaining the secret of stone formation than any of the various other theories.

Symptoms Pain, haematuria, nausea and vomiting, urinary frequency and urgency are the predominating symptoms in the order of their frequency. There is no definite order as to the sequence of their appearance, usually either pain or haematuria appears as the primary subjective symptom, Fig 4 followed by the gastrointestinal and the urinary symptoms in the order named. It is always well to remember however, that any variation in the type or sequence of symptoms may occur.

Pain is a very striking and usually the most prominent symptom. The onset may be very sudden or it may be more gradual, beginning as a sense of uneasiness, followed by a dull ache of increasing intensity, and this latter type is more likely to be the case when the patient has repeated attacks. Fig 5. There may be remissions of severity with a very severe attack, or a constant dull ache with periods of very sharp accentuation. Fig 6. About the severity of the pain there is seldom any question either in the mind of the patient or of the onlooker. The sufferer moans or cries and rolls or crawls about the bed or on the floor constantly seeking relief in change of posture and position or by making pressure in the flank. Women who have had children say that the pain with stone is worse than that of childbirth, and even if this is an exaggeration the mere expression of such a comparison serves to fix in

Fig 4—Right ureter contains a stone which has not blocked the flow of urine. Haematuria might be profuse but no pain would be noted until obstruction to the flow of urine occurred as illustrated in the left ureter where a spasm of the lower end of the ureter has firmly grasped the calculus

one's mind the character of the suffering. The writer is firmly of the opinion that the pain is due to distention of the pelvis and ureter with urine, the kidney continuing to secrete even when the escape of urine downward is prevented by a stone or other lesion causing a complete obstruction, in these cases by a stone completely filling the lumen of the ureter, either by its size and shape or because it is firmly grasped in a spasm of the ureteral muscles and it is quite probable that spasm is always a factor. Fig 7. It is highly improbable that trauma of the ureteral mucosa incident to movement of a stone is an important factor in causing pain. Trauma incident to instrumentation is seldom complained of, but distention of either the ureter or pelvis with injected fluid will instantly cause pain exactly simulating that of calculus colic. The duration of the pain varies from minutes to hours or even longer. As we usually see cases the pain persists until influenced by medication, but occasionally persistent retching seemed to be followed by relief from pain and again it ceases spontaneously.

The onset of the pain is usually without demonstrable cause, and although exertion, rapid movements, etc., may seem to influence the onset, as often as not the attack will begin during the night

while the patient is asleep in bed. One factor that would seem to have more than a casual relationship from the frequency of association is the onset of pain after a ride in a railroad coach or an automobile.

The location of the pain also varies somewhat but when severe the maximum intensity is always in the costovetebral angle. Radiation of pain is common, most frequently downward and forward to the testicle or labia, less frequently to the groin, penis, labia, thigh or knee, or anteriorly to the upper abdomen or even to the shoulder. Occasionally a calculus in the kidney pelvis before it causes complete blocking to urinary outflow, may be associated with a dull ache in the groin of the same side as its only subjective symptom.

Despite exceptions to this rule it is not possible to accurately locate the position of a calculus from the type or location of the pain or the direction in which it radiates.

Gastro-intestinal symptoms. Symptoms of gas-

Fig 5—Intermittent hydronephrosis due to a calculus represented in a major calyx. No subjective symptoms present until the calculus moves to the ureteropelvic junction causing complete obstruction, pelvic distention and a typical renal colic. During the attack of colic the urine may be normal or contain a faint trace of albumen. In the intermissions the urine would contain pus and blood cells in varying amounts.

Fig 6—Large calculus impacted in ureter, with chronic partial obstruction and production of a hydronephrosis. Urine trickles past the stone so that there is not a complete block, thus there may be no acute symptoms.

tro-intestinal disturbances are frequently associated with the severe attacks of renal colic. Rarely we find a patient who has a distinct diarrhoea either immediately preceding or accompanying the other manifestations. Nausea is present in a large percentage of cases and vomiting is a factor in nearly all severe attacks. The vomiting is apt to be severe, so that everything ingested is returned and even severe retching with the emesis of bile when nothing is taken by mouth. So prominent may these symptoms be that one could be easily misled into mistaking these gastro-intestinal symptoms as indicative of gastro-intestinal pathology rather than that a calculus was the basis of the disturbance.

A feeling of abdominal distention with gas is often present and a very common experience is

Fig 7—Calculus acting as a ball valve which when seated causes complete obstruction and colic. At other times may allow escape of urine with absence of subjective symptoms

to hear a patient state that while there is no desire to stool they think they would feel better if the bowels did move. The consideration of these symptoms of gastro-intestinal disturbance is of particular importance when differentiating between a stone and an acute appendix.

Urinary symptoms. Increased frequency and urgency of urination, either associated or alone may be present with a stone located in any portion of the ureter or in the kidney pelvis. When it occurs for the first time after previous attacks

of pain or when it is noted after a paroxysm has lasted for some time it is usually indicative of the passage of a stone down the ureter to a point close to the bladder. With the groin pain at times associated with stones in the kidney pelvis, and of which mention has already been made, the occurrence of urinary frequency under these circumstances is probably the only localizing subjective symptom that is at all consistent.

Inability to empty the bladder may be complained of. Usually on analysis it will be found that there is no retention, but that markedly increased frequency causes an attempt to urinate every few minutes with the discharge of only a very small quantity of urine and that is mistaken by the patient for inability to empty a bladder believed to be full. Chills, chilly sensations and fever are occasionally present but seldom are prominent.

Objective symptoms. Fever may be present to a slight degree. The pulse rate is apt to be increased proportionate to the intensity of the suffering. Of the objective symptoms, costo-vertebral and abdominal tenderness and rigidity are the most prominent. While usually not so marked as when found with acute intraperitoneal conditions it must be remembered that in some instances they may so closely simulate the latter as to make practically impossible a differential diagnosis. Particularly will this be true when as not infrequently happens an increased leucocyte count with a high polynuclear percentage is present with an uncomplicated stone. In a series of cases recently studied a leucocyte count of 15,000 was not uncommon and one case went above 30,000.

The X-ray is our great reliance for an accurate diagnosis and for localization of a stone but even here unfortunately negative results may count for little. Small or soft stones may not cast shadows and the size of the stone is no index of the severity of the symptoms. Happily with the improvement of technique and apparatus roentgenological examination is becoming more and more valuable as a diagnostic aid.

The cystoscope is of invaluable aid both in diagnosing and locating a stone and in giving information about the kidney on the affected and opposite side as well as disclosing other pathological complications. Occasionally a stone will be seen at the ureteral orifice making an absolute diagnosis possible.

Changes in the appearance of an orifice and of the mucosa about the orifice is of decidedly less importance than one would be led to believe from the literature. If changes are present they may be of considerable corroborative significance, but the absence of any change is of absolutely no value as evidence against the presence of stone and it is quite conservative to state that normal appearing orifices are in the majority.

When complete obstruction occurs in any part

of the tract above the bladder no urine will flow from the orifice. Observed during an acute paroxysm the ureteral orifice will be seen opening and closing exactly the same as it does incident to the discharge of urine into the bladder, differing only in the fact that no urine escapes.

A catheter may be obstructed by a stone. This offers very strong evidence as to the nature of the lesion and the exact location of the stone. When a large catheter is obstructed a smaller one may be manipulated past the obstruction and to the pelvis. Then residual urine may be found in the pelvis, the amount depending upon the length of time the obstruction had persisted and the completeness of the obstruction. The urine under these circumstances is usually of very high specific gravity and is apt to contain albumen and casts. However, it cannot be too strongly emphasized that a catheter may slip past even a large stone without giving any suggestion that a stone is present. A wax tip on a catheter passed up and down a ureter may show scratch marks on its surface from contact with a stone. This method is not wholly without chances of error and the finding should be considered only in conjunction with the other symptoms.

The nearest we come to perfection of diagnosis is by the use of a combined cystoscopic and roentgenological examination. With an opaque catheter in the ureter, stereoscopic X-ray plates will show a constant and close juxtaposition of the stone and the catheter shadows and with the few exceptions noted elsewhere such demonstration is an absolute prerequisite before operation.

Treatment. Treatment will depend principally upon the phase of the condition in which we find the patient, and to a lesser extent upon the general condition of the patient and by co-existing conditions. Seen in an acute attack of colic immediate relief is necessary and for this purpose morphine hypodermatically and in sufficient dosage is almost always necessary. It is very seldom that any treatment short of the injection of morphine will be of value and usually it is a waste of time to make use of lesser measures.

Chloroform by inhalation has been mentioned as needed in some instances, and while it has never been necessary in the writer's experience to resort to this, it cannot be too strongly emphasized that relief from the pain must be secured. Indeed, it is hardly necessary to emphasize this point to one who has seen a patient in the agony of a renal colic, whether the colic be due to stone or some other type of obstructing lesion.

Palliative measures, heat, locally by a hot water bag or poultice or by a full hot tub bath, acetanilid, phenacetine and drugs of such type are usually totally inadequate and attempts to give relief by such measures are complete failures, only prolonging the suffering. Such measures are justifiable only when used as adjuvants to the morphine.

Withholding morphine with the idea that a cer-

tain amount of pain is necessary for the expulsion of the stone is not justifiable; indeed, progress of the calculus down the ureter takes place probably to a greater extent in the intervals between attacks than during the colic.

A marked diminution in the amount of urine voided may occur and this may go on even to the point of complete suppression. In the presence of this calcaous anuria, operative intervention may have to be considered, remembering always that the index of the gravity of the situation is the diminution of the amount of urine and not the usual signs of impending uraemia, as the latter may be absent until just prior to a fatal termination.

Anuria may be due—

- I To the blocking of a single ureter
- II To simultaneous blocking of both ureters
- III To blocking of the ureter of the good kidney in the presence of a damaged opposite kidney, and,
- IV Possibly, to reflex suppression in the unblocked, undamaged kidney

Whatever the cause relief of the block is imperative and is best accomplished by drainage of the kidney pelvis on the affected side, by pyelotomy usually, but rarely it may be accomplished by an indwelling ureteral catheter. Removal of the stone may well be left for a later time when the critical period has been passed.

In the intervals between paroxysms decision will be made as to the course to be followed. Our subject is removal of the stone and here we have to decide between surgical intervention and expectant treatment, as stones are removed,

- 1 By spontaneous passage into the bladder,
- 2 Aided by cystoscopic manipulations,
- 3 By operation

In addition to the size and location of the stone, the age and general condition of the patient and the frequency and severity of the attacks are but a few of the considerations that present themselves.

The economic position of the patient may be of great importance, for given a patient upon whose daily earnings himself and others depend, it may be better in a doubtful case to advise operation with complete relief and an early return to his wage earning status, rather than to subject him to a period of waiting, indefinite both as to length and outcome. This must not be construed however as an argument for early operation except where the size of the calculus justifies doubt as to its spontaneous expulsion.

Unfortunately we have no scale of measurement to apply in the decision of such cases but must decide each case on its own merits in accordance with all the factors present and our own knowledge of the clinical course of like cases. Nor have we any premises upon which to prognosticate the number of attacks of colic that will occur before the stone will be expelled into the

badder, nor the length of time that will elapse before that happy outcome is consummated. Fluids in abundance, dietary restrictions, attention to the eliminative functions and rest are all logical therapeutic suggestions that are applicable. Heat as already suggested may help in mild cases and it augments the effect of morphine in the more severe ones.

Benzyl benzoate relaxes involuntary muscles and while it is doubtful that in itself it is of any practical value it may be of help as an adjuvant. Against its use is the distention of the abdomen that is of frequent occurrence. Spirits of turpentine in 10 minin doses, three times a day has probably the greatest reputation for exerting an actual influence upon the passage of stones, some writers stating that more stones pass with its use than without it. Glycerine in slightly larger dosage is probably second in popularity. Coconut milk and watermelons are but two of the many additional remedial agents that have been and still are seriously presented as possessive of beneficial therapeutic influence.

When we consider that a certain and probably a large percentage of those with calculi have attacks of renal colic and pass their stones without a diagnosis being made and that in those in whom a diagnosis is made a large percentage expel the stone spontaneously without even any cystoscopic help, it must be apparent that the percentage of stones that pass must be extremely large, and therefore any form of medication or plan of non-surgical treatment that may be instituted is most likely to be followed by the passage of the calculus.

Therefore any treatment believed to be successful would have to be tried on a very large number of patients, with proper controls, before the administration of such medication could be accepted as other than coincidental to the spontaneous expulsion of a calculus, rather than being a causative factor. It may well be questioned whether any treatment of internal medication has ever had any influence in preventing the formation or aiding the expulsion of calculi. The sincerity of any observer is no index to the accuracy of his observations or the logic of his deductions if his conclusions ignore the variables and laws of chance so apt to be important factors in all of our therapeutic problems.

Through the operating cystoscope we can cut with forceps or burn with the high frequency current, the intravesical portion of the ureter, thereby increasing greatly the size of the orifice and thus facilitate the passage of a stone into the bladder. Oil may be injected into a ureter to lubricate the path of descent of a stone. We pass successively larger bougies up the ureter hoping thereby to dilate and thus facilitate passage, and use various ingenious instruments of the type of the Lewis dilating forceps to the same end. These manipulations may tone so that its long

axis is more nearly parallel to the long axis of the ureter, they may break calculi into smaller fragments, and both of these results tend to promote expulsion.

Beyond this it is doubtful if anything practical is accomplished. The writer has on innumerable occasions been able to dislodge a calculus from the lower end of the ureter and either break it up in smaller fragments in the bladder or remove it whole with forceps, to the great joy of the patient and the not inconsiderable satisfaction of the operator. Such a happy termination of a calculus case is dramatic in the extreme but possibly it only anticipates by a short time a spontaneous happening.

If a stone is impacted by constrictions in the calibre of the ureter or if it is of such a size as to preclude its discharge into the bladder operative intervention should not be delayed. Fig 7 A pyelotomy, nephrolithotomy or ureterolithotomy as indicated by the position of the stone should be done. Before advising an operation every possible precaution must be taken to verify the diagnosis and establish the presence of a stone. With very few exceptions a shadow must be demonstrated and proven to be either in the kidney pelvis or in a ureter by a combined cystoscopic and roentgenological examination. Too much care cannot be taken to establish a positive preoperative diagnosis both for the patient's welfare and the surgeon's reputation.

There are few situations that will cause more embarrassment than the failure to find a calculus at operation after a preoperative diagnosis of stone. A good rule to remember is that a stone that will not produce a shadow on an X-ray plate will in all probability pass into the bladder. As possible exceptions to this rule the two following cases may be cited, each illustrating the superimposition of a stone shadow upon that of bone.

A 32 year old clergyman came under observation in October 1919. While with the A. E. F. during the war he had his first attack of severe pain in the left flank. The onset was very acute, the pain very severe, nausea and vomiting were prominent symptoms. The pain radiated down into the left testicle. Red blood cells were present in the urine. Many subsequent attacks followed during each of which he was completely incapacitated. In the intervals between attacks he was perfectly well. Repeated roentgenological examinations were negative as were several cystoscopic examinations. After his return to the United States he was sent to the Walter Reed Hospital for further study, and although repeated examinations were made no definite diagnosis was established, the attacks of colic in the meantime persisting. When seen by the writer further X-ray examination was negative. The general physical and laboratory examinations were also negative except for the presence of a few white blood cells in the urine. A further cystoscopic examination

was made showing a normal bladder. Catheters were passed to either pelvis readily, no obstructions were noted, and no residual urine was found in either pelvis. Each kidney secreted clear urine rapidly. No increased capacity of the left pelvis could be demonstrated and the urine from this side differed from the other only in the presence of a few white blood cells.

Distention of the left pelvis with fluid caused pain which the patient identified as being exactly the same in character and location as that experienced by him during his attacks of colic. A diagnosis of renal colic due to an intermittent obstructing lesion, probably a calculus, was made and operation was advised as it was felt that if a stone was not present some other lesion would be found to explain the symptoms and as the condition had persisted for such a long period an exploratory operation on the kidney would be justified. However, as the patient desired further attempts to make a more positive diagnosis additional X-ray exposures were made and as a result of a particularly long exposure a shadow was finally found superimposed upon the shadow of the last rib. Operations resulted in the removal of the stone and relief from the symptoms.

Another patient, a man 33 years old was referred in September, 1921, for diagnosis. In February of that year a profuse hematuria had lasted for a few days, without other symptoms. No treatment was instituted other than rest in bed and a bland diet. Two months later the patient applied for life insurance and was rejected because the urine contained albumen, casts, and red and white blood cells. Three weeks later the same conditions were found. Two months after the second and nearly three months after the first examination the urine was reported almost normal. About this time the patient noticed a stiff back which varied in severity during the two weeks it persisted. In August, six months after the hematuria, he had a severe attack of pain in the right upper quadrant, lasting, with periods of remissions for seven hours and then ceasing suddenly. He had several chills of moderate severity, slight fever, continuous nausea and severe vomiting while the pain was present. During the evening the pain recurred and although not so severe it was feared that an acute appendix had ruptured. The patient was transported a considerable distance to a hospital. A white blood count was made showing 32,000 white cells with a high polynuclear percentage. However, as blood and pus were found in the urine his symptoms were considered to be due to some condition in the urinary tract and the patient was kept under observation for a few days during which time his subjective symptoms cleared up and the blood count returned to normal. Several X-ray examinations were reported negative. Three weeks later at a cystoscopic examination an obstruction was demonstrated 14 cm up the right ureter

while on the left side a catheter passed to the kidney pelvis. Although this obstruction prevented the passage of the catheter upward it did not prevent the urine from coming down and specimens were obtained from each side. The specific gravity, total acidity, and percentage of urea, ammonia chlorides was identical from each side. Cultures from each side were sterile. The phloridizin test was positive on each side in 15 minutes, the phatalein test positive on the right in seven minutes, from the left kidney in five minutes, thus being practically the only difference noted. The catheter in the right ureter was withdrawn to permit the use of a smaller one in an attempt to get past the obstruction, but spasm at the ureteral orifice prevented the reintroduction of any instruments. At later examinations the same results were obtained and it was never possible to catheterize beyond the point of obstruction. Roentgenograms taken with opaque catheters in the ureter all showed the catheter reaching to approximately the same point, just above the lower border of the ilium, so that if a calculus were present its shadow would be superimposed upon that of the bone and under these circumstances it would be extremely difficult to differentiate the two shadows. The cystoscopic diagnosis was "An obstructing lesion in the right ureter, probably a stone, 14 cm above the bladder." Operation was advised in this instance on the ground that even if no calculus was found the lesion that was present required treatment. At operation a calculus was found and it was so impacted that it could not be moved either up or down the ureter.

Factors such as the frequency and severity of the paroxysms and the effect upon the general health of the patient may have to be considered irrespective of the size and location of the stone. A young woman of intelligent mentality came under observation in 1922, giving a history of repeated and very severe attacks of pain during the preceding four years. A positive roentgenological and cystoscopic diagnosis was made of a stone close to the bladder and in view of the long duration of the symptoms and failure to cause any change in the position of the stone through cystoscopic manipulations, operation was advised but refused. For a period of another year the patient had repeated recurrences at frequent intervals. Some of the attacks incapacitated her for days at a time. Then after a particularly severe paroxysm of pain of some twelve hours' duration she expelled the stone.

It is probable that the pain endured during this period and the danger she incurred of kidney damage were much greater than would have involved in an early ureterolithotomy. As in this instance patients may refuse operation, not infrequently quoting the experience of friends who have passed stones. Opposed to this will be patients impatient for operation after a first attack of pain who will state that they prefer the risk

of operation with the certainty of relief to the uncertainty of waiting. In such instances it would of course be folly for us to allow such impatience or desires influence us against our own surgical judgment.

The operative results are very satisfactory as a rule. The stone is removed, relief from the symptoms is assured and convalescence is usually uneventful. Some leakage of urine from the wound may appear, as a rule it is for a short time only, and the tendency is for the incision in the ureter to heal kindly even if not sutured. That exceptions to this rule may occur is to be expected. A young woman, 24 years old, of splendid physique and otherwise good health came under observation giving a history of colic and hamaturia, suggestive of calculus. The diagnosis was verified by stereoscopic plates with an opaque bougie in the left ureter. Two large stones were present, one close to the bladder, the second several cm above the first. It was impossible to pass a catheter above the stones so that no information was obtained as to the condition of the kidney. The upper stone was readily removed after isolation and incision of the ureter. The lower one however, was fixed in its position and could not be brought up to the ureteral incision.

Therefore the ureter was again incised immediately over the stone and the latter removed. Both ureteral incision were sutured with No 1 chromic gut. Cigarette drains to each ureteral wound were removed in 48 hours. Three days later the patient's temperature had reached 103° F and while no tenderness was present the skin about the wound appeared dusky. The sutures were removed and the wound reopened liberating a quantity of thick fluid. After this much pus and urine drained from the wound, the patient was quite sick, and had a septic temperature and a rapid pulse. As we had no knowledge of the condition of the kidney the question of a pyonephrosis came up. If such had been the case a nephrectomy would be indicated, but at a cystoscopic examination at this time a large catheter was passed up the ureter and an abundant flow of clear urine obtained. The chemical tests showed good functional activity and the urine contained very little pus. Thus a good kidney and a good tract from the kidney to the bladder were demonstrated and with this knowledge an expectant plan of treatment was followed with a good result, although the patient did not leave the hospital until six weeks after the operation.

ELECTIVE VERSION AND EXTRACTION*

By PAUL T HARPER, M D, F A C S

ALBANY, N Y

THE necessity for standardizing the indications for delivery by Version and Extraction and for prescribing the important steps in their conduct has prompted choice of the above subject for presentation before the Section, and what follows is offered as a contribution toward such ends.

For the contentions made and for the expedients employed in effecting delivery, the writer claims no originality. All are familiar, each being supported by accredited authority, and, for this reason, their exposition might appear unnecessary. But important clinical facts and matters of personal experience relative thereto cannot be restated too often, and this fact alone justifies their repeated presentation.

Internal Podalic Version is the procedure by which the child, presenting commonly by the head, is turned in utero by grasping its feet and making them advance until the knees are born. Appearance of the knees completes version, the child is "turned" when head, chest, abdomen, and lower extremities have been brought into line.

Version of the kind may well be followed at once by Extraction, and the latter practice is so common that breech extraction should be con-

sidered along with internal podalic version, although the two are separate and distinct operative procedures. "Internal Podalic Version and Breech Extraction," therefore, more accurately designates what is done when the child, presenting by the vertex, is made to advance and is born feet-first, than does the more familiar term "Delivery by Version."

Version and Extraction (shortening the accurate designation for purposes of discussion) have been practised from the earliest times and, if abdominal section be disregarded, they were the only means of artificial delivery available before advent of the obstetric forceps. Use of the latter unquestionably lowered mortality and morbidity attendant upon the earlier procedures carried out without the aid of anesthetics and without regard for sepsis, and version and extraction fell into more or less disuse, being looked upon as emergency measures the hazards of which might be assumed only in extreme cases. Such in the main has been the attitude of the profession for centuries, and it is only within the last decade that version and extraction have been strongly advocated as elective procedures.

The heartiest endorsement comes from a single source and so persistent and strong is it that its advocate urges practice of version and extraction

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, May 13, 1925

not only in preference to extraction by forceps but also as the method of choice in terminating the overwhelming majority of labors regardless of actual need for operative interference

Whether such general employment of version as is advocated by Potter is or is not justifiable is a highly debatable question. However, that the utility of version and extraction has been immeasurably broadened within recent years, that valuable contributions to the technique of the operation have been made, and that for each a single operator is in the main responsible are propositions that may not be dissented from, and the actual place of version in obstetrics is the important clinical question of the day if for no other reason than because a distinguished obstetrician and a teacher of wide experience raises it.

The problem may be stated no less accurately as uneventful delivery and the usefulness of version and extraction in bringing it about, and the latter procedures are presented as contributions toward making delivery uneventful by actually decreasing the mortality and morbidity that might otherwise be expected were cases on the one hand, left wholly to nature or, on the other, accorded more conventional operative treatment.

At the outset, it is insisted that the writer is neither handicapped by prejudice against widening the field of version and extraction simply because the procedures are less conservative than the familiar methods of operative delivery of a generation ago nor, on the other hand, does he subscribe to "habitual version" simply because he has seen (which it has not been his good fortune to do) a master of the art accomplish entirely satisfactory results in cases wherein one of less skill and experience might be expected to have failed. However, this discussion is entered upon with the firm conviction that the utility of version and extraction is far wider than the majority of authorities are ready to concede—a conviction that is strengthened by knowledge that the speaker's own results in terms of mortality and morbidity have improved with wider application of the principles of internal podalic version and breech extraction.

The most striking feature of version and extraction is that their performance is a complete reversal of the natural process by which the child is born, and one of them, namely breech extraction, invariably entails risks to the child that the conservative obstetrician aims to minimize by performing prophylactic external cephalic version in primary presentation by the breech. Dangers in breech extraction *per se* arise from possible delay in delivery of the after-coming head, resistance to the advance of which is invariably occasioned by the fact that it is an unmodelled head that must engage, descend, and be born within a relatively short interval following birth of the navel.

Version and extraction, therefore, under con-

ditions that have denied the head the advantages of satisfactory moulding are procedures entailing risks to the child that one may unhesitatingly assume if the emergency warrants it but that one is not justified in assuming from choice.

Herein is believed to lie the fallacy of "elective version (and extraction)" as practiced by Potter, by whom the procedures are carried out at the beginning of or early in the second stage of labor and preferably after artificial rupture of membranes, under these conditions, maximum moulding of which available forces are capable has yet to occur. The procedure, therefore, entails risks which skill and experience can and doubtless do greatly minimize but which are so obvious that conservative practice will in all probability never subscribe to its performance as the method of choice in accomplishing delivery.

However, there are conditions wherein version and extraction are definitely indicated and at such times their benefits are fully realized only as the procedures are "elective" in the strict sense that they are carried out, from choice rather than from necessity, at a time when mother and child are good risks.

Returning to consideration of the combined procedures, it is true that there are difficulties and some dangers associated with the performance of version and of the extraction that follows, but it is no less a matter of fact that there are peculiar advantages attendant upon producing advance and delivery of the child by traction on the legs under certain conditions and, because of this, that version and extraction are on occasion procedures of choice.

Version entails the risks of infection, rupture of uterus, traumatic separation of placenta, prolapse of cord, and fetal fractures and dislocations, while breech extraction is always attended by the dangers of cervical and perineal laceration, fractures, paralyses, head injuries to the child, and asphyxia from delay in delivery of the after-coming head. These result in practically every instance from disregard for certain elementary principles of procedure. They are, therefore, highly preventable accidents, the ever-present dangers of which do not limit the availability of version and extraction as much as they emphasize the wisdom of adequate training and skill on the part of the operator who attempts them.

Under certain conditions, traction on the legs and extraction by the breech offer positive advantages over the application of forceps and on rare occasions, over spontaneous advance and delivery by the vertex.

The most conspicuous instance is offered by incomplete dilation of the cervix and high arrest of the presenting-part. Pelvic contraction invariably complicates the situation and it is quite as often relative as actual in type. For purposes of delivery, a pelvis with normal measurements is "relatively contracted" when over-large fetal

diameters must pass through it, and diameters of the kind are met in the deflexion attitudes as well as in prolonged pregnancy regardless of presentation. The primary difficulty, therefore, is disproportion, it is increased by thickness of the lower segment, with its incompletely dilated external os, that encircles the head, and arrest results. Spontaneous upward advance of the lower segment over the blunt presenting-part and complete dilation have already failed, and, if the case is left wholly to nature, the lower segment becomes retracted or the cervix becomes oedematous and possibly incarcerated.

Granted that artificial advance is indicated and, further, that forceps on the head is the alternative method of producing it, version and extraction present the following distinct advantages: first, complete dilation is easily accomplished under surgical anesthesia that version calls for (as complete relaxation is possible although undesirable as a preliminary to forceps extraction), second, upward advance of the fully-dilated cervix and the thinned-out lower segment is the natural consequence of passage through them of the smooth, roughly-cylindrical fetal body (contrasted with the irregularly-rounded but blunt head), and, third, the manner of advance of the head is such that its broadest transverse diameter (the biparietal) follows rather than precedes the shorter bimastoid diameter through the inlet with the mechanical advantage attendant upon causing a wedge-shape body to advance against resistance by its point rather than by its base.

Of the foregoing, the second is possibly the most important advantage, and it is believed to explain the frequency with which the undilated but dilatable cervix escapes laceration during version and extraction as contrasted with the damage done by advance of the blunt head and by the edges of the forceps blades when delivery is instrumental.

Skilfully performed version and extraction unquestionably occasion less cervical trauma than does the high forceps operation in equally competent hands, and because the after-coming head need never be called upon to advance through an incarcerated and edematous cervix in breech extraction, while in every high-forceps operation and in many of the high-medium variety disproportion between pelvis and passenger is increased by thickness of the enveloping lower segment, it may be argued that version and extraction are less dangerous to the child.

With the patient in a clinical second stage (preferably with membranes ruptured) long enough to be assured that the cervix is completely dilatable and that the presenting-part is satisfactorily moulded, delivery by version and extraction is preferable to high-forceps application. If one hesitates to make the procedure elective, it is imperative that it be carried out after a

single unsuccessful attempt at effecting delivery by traction on forceps.

In this group of cases are found posterior positions of the vertex, and bregma, brow, and face presentations with the biparietal diameter above the inlet—in fact, all cephalic presentations arrested high up wherein vaginal delivery is not contra-indicated because of pelvic contraction.

It is in high arrest of the presenting-part that cord complications are most common. Following rupture of the membranes, prolapse of cord along-side-of the presenting part occurs when the latter is momentarily displaced upward. The introduction and application of forceps not infrequently produce just such a result unless the precaution is taken to immobilize the head at the inlet while the instrument is being adjusted, and it is only through careful fetal-heart auscultation that occurrence of the accident is ascertained. It is true that upward displacement incident to version may result in cord advance, but the operator feels the prolapsed cord at once and his hand is in position to replace it at once or to accomplish immediate delivery when the latter is called for. Undiscovered cord prolapse is believed to be responsible for much of the fetal mortality incident to high-forceps operations that wider application of version and extraction can be counted upon to decrease.

In treatment of the persistent occiput-posterior arrested in the mid-pelvis, the choice between version and forceps rotation and extraction is largely a matter of individual preference that, in turn, is determined in great measure by the training and skill of the operator. However, in this connection the following are reasonable contentions. All other things being equal, the child is invariably a better risk advancing by the head than by the breech, and, in presence of the disproportion that commonly makes rotation difficult, careful attempts at instrumental rotation that may be carried out slowly and, therefore, with a minimum of violence are preferable to the more rapid and more forceful extraction that version under the circumstances invariably entails. One's easily-acquired enthusiasm for version must always be tempered with proper appreciation of its increased responsibilities.

In view of what has preceded, conservative practice would seem to call for a single, skilful attempt at instrumental rotation and advance, version and extraction being carried out unhesitatingly when the procedure of initial choice has proved unsuccessful.

After internal podalic version, the operator has quite perfect control over delivery of the child, and he can produce a relatively rapid advance, when indicated, with minimum danger to the child because tractile force is applied to the body at the sturdy pelvic girdle, while undesirable bony and lower segment pressures are exerted along changing levels of the child's body as but-

tocks, abdomen, chest and head advance. In forceps extraction, on the other hand, the head is subjected to firm, localized pressures throughout advance and tractive force is transmitted to the body at the structurally-weaker and more vital neck.

Accordingly, delivery by version and extraction is advisable in cases of impending fetal or maternal death from hemorrhage (provided the cervix is first removed as a barrier to advance), in cases of irreducible prolapse of cord with the head high and the cervix dilated or dilatable, in cases of premature labor due to hydramnios or multiple pregnancy where cord complications are common, and in cases where digital dilation under complete surgical anesthesia has been practised for the excellent purpose of terminating pregnancy complicated by rapidly advancing toxemia.

In labor obstructed by tonic contraction of Bandl's ring, version and extraction are indicated in cases where the ring is found in advance of the presenting part, for the reason that the latter is invariably high or actually disengaged. With the ring encircling the neck, the procedures have at least one definite advantage over delivery by forceps, namely, that version is possible only after such complete relaxation of the ring that subsequent extraction can be accomplished against a minimum of resistance and therefore with least effort. Forceps extraction, on the other hand, involves the risk of bringing about complete disappearance of the ring by advance of the shoulder girdle through it, and the latter requires increased tractive force that subjects the child to dangerous forceps-pressure on the head.

Danger of undesirable cerebral pressure is to be considered when the relatively-compressible head of the premature child is called upon to serve as an actual cervical dilator. The latter occurs when membranes rupture, before complete dilatation, and strong contractions force the head well into the partially-dilated cervix. The combination of surgical anesthesia, manual dilatation, version and extraction not only relieves pressure of the kind but it also gives promise of safer delivery than if the occasional case of the kind were left wholly to nature.

In some cases of multiple pregnancy, delivery by version and extraction is the method of choice. In double vertices with heads above the inlet, the dangers of cord complications and of locked heads that are not uncommon even in spontaneous advance, are obviated when head of the first child (so designated because its level is slightly in advance of the other) is displaced and held upward while version and extraction are done upon the second. In delivery of the second child presenting by the vertex, undesirable delay occasioned by inertia following spontaneous or artificial delivery of the first is eliminated and the second stage is terminated with minimum risk of

cord prolapse as the child is turned and made to advance by the breech.

Finally, internal podalic version is indicated in practically all transverse presentations seen late in the second stage with fully dilatable cervixes and before the uterus has become tonically contracted. In cases of the kind, a shoulder presents and impaction is the inevitable consequence of expectancy. Dangers of version and subsequent extraction are negligible provided the membranes are still intact, they are increased when the liquor amni has escaped, and they are grave when a tonically-contracted uterus complicates the situation. In transverse presentations seen early, introduction of a large hydrostatic dilator is the procedure of choice; it makes possible the performance of external cephalic version that gives promise of ultimate spontaneous delivery.

Attempt has been made to show the extent to which version and extraction are elective procedures. By as much their utility is broadened, and benefits accrue to mother and child because neither has been subjected to the dangers of persistent and unsuccessful attempts at forceps extraction or to those resulting from protracted second stage.

Version and extraction should benefit mother and child. Therefore, they may not be attempted under conditions making their conduct dangerous even though an emergency seems to demand heroic measures. It may not be amiss at this point to state the simple proposition that artificial delivery is the only surgical procedure entailing the possibility of a 200 per cent mortality. No less to the point would seem to be the contention that, in sheer hazards to mother and child, no method of operative delivery even approaches untimely and unskilfully performed version and extraction.

The procedures are contra-indicated in tonic, or "capped", uterus, in retracted uterus, and in tonic contraction of Bandl's ring, wherein turning may result in rupture of the uterus or in injury to the child, and in pelvic contraction, either relative or actual, of a degree making delivery of a living child by the vaginal route improbable. Of types of contracted pelves, the flat justo-minor offers greatest resistance to passage of the after-coming head. Shortening of all diameters denies the head the advantages of lateral displacement by which its passage through the inlet of a simple flat pelvis is facilitated.

The abnormalities considered are primary causes of obstruction, so designated because delivery may not or cannot be accomplished in their presence, but, of them, retracted uterus and tonic contraction ring respond so satisfactorily to treatment by profound surgical anesthesia that version and extraction can be done with reasonable safety following their relief, provided associated conditions warrant their practice.

Finally, version and extraction are contra-in-

licated in two additional groups of cases first, those in which simpler and less dangerous procedures give promise of shortening the second stage and decreasing maternal suffering as satisfactorily as could version, and, second, those in which reasonable opportunity has not been offered the head to accommodate itself to the shape and size of the pelvic cavity by moulding. In other words, the practice of version and extraction is contra-indicated where a simple forceps extraction or conservative stimulation by pituitary extract gives promise of uneventful delivery, while, for arbitrarily carrying out the procedure at the beginning of the second stage, before rupture of the membranes and even before the patient has been afforded an opportunity to terminate her labor spontaneously, there would seem to be no excuse. Under such conditions, the procedures are "elective" only in the sense that the operator chooses to carry them out the truly elective operation is one that is selected because it is safer than expectancy or than some other procedure he might select. It is only by performing an unnecessarily large number of abdominal sections that one can make wide use of early second-stage version and extraction and present infant-mortality statistics that are at all satisfactory. The size of the unmoulded head can be disregarded when it is to be delivered through the uterine incision.

The conduct of internal podalic version is governed by the well-defined principles that follow.

First, intra-uterine exploration is permissible only as perfect aseptic precautions are observed. Because an extensive and highly vascular area is exposed to direct contamination from without, it is imperative that hands, arms, and gloves, and particularly the field through which they are introduced, be made and kept surgically clean. In vulnerability and seriousness of results of infection, endometrium and peritoneum are quite alike.

Second, there may be no uterine obstacle to turning. While such persistent pathological states as retraction, tonic uterus, and tonic contraction-ring contra-indicate version, even normally active uterine muscle almost invariably acquires tone as soon as a hand is inserted in the lower segment, and undesirable force is required to overcome uterine resistance unless the precaution is taken to secure deep, surgical anesthesia before the uterus is invaded.

Third, the occurrence of accidental separation of the placenta and cord prolapse must be guarded against. They increase the hazards ordinarily associated with version, even though the cervix is fully dilated and immediate delivery is possible when they occur.

Fourth, the position must be known before the uterus is invaded. The dangers of placental separation, of cord pressure, and especially of infection are minimized as the operator's hand is

carried directly to the point at which he may expect to meet the feet.

Just how each step in the performance of version should be carried out is relatively unimportant provided one is governed by the principles briefly considered. For instance, choice of anesthetic and choice of hand with which to grasp the feet are details that individual preference, based upon experience, may be permitted to dictate, but that the anesthetic actually produce complete relaxation before version is attempted and that the hand in the uterus be used for purposes of version rather than intra-uterine exploration are features of the operation in regard to which there may be no difference of opinion.

The following details of procedure are recorded because, first, they meet the requirements of version and, second, they have been found helpful in its successful conduct.

- 1 The patient's buttocks are brought to the edge of the delivery table. Her legs are separated and each is held, with foot just below table level, by an attendant who supports a foot by one hand and a knee by the other. The advantages are as follows: the patient lies in a modified Walcher position that facilitates version by lengthening the antero-posterior diameter of the pelvic inlet, the maternal position can be easily and speedily changed as conditions warrant, and, lastly, the patient strains against arms that can yield rather than against stirrups that are fixed and the field is correspondingly less disturbed. When attendants are unavailable, the feet rest upon chairs placed with backs to the delivery table.

- 2 The vulvo vaginal outlet, perineum, inner surfaces of thighs, pubes and, lastly, anus are scrubbed with soap and water and flushed off with antiseptic solution, the bladder is emptied by catheter, towels are draped about the field, and a sheet of medium size is placed over the abdomen.

- 3 Continuous administration of ether and the foregoing preparations are begun at the same time. The excitement stage is passed and a quiet field assured by the time the patient is draped. The anesthetic of choice is ether. It relaxes uterine muscle more quickly and more completely than chloroform or nitrous oxide and it is safe for the prolonged administration that cases of retraction or tonic contraction-ring demand. Further, the primary, fetal-heart-stimulating effect of ether is of decided advantage where version is to be followed by immediate extraction. It is desirable that the anesthetic be administered slowly. No attempt either at digital dilation or at version may be made until the musculature is completely relaxed and, in the presence of even slight retraction, until beginning pupillary dilation is noted. Cases of tonic uterus and advanced retraction not uncommonly demand 30 minutes of surgical anesthesia before version may be attempted, and,

although one may hesitate to subject the patients to such deep and prolonged anesthesia, the hazards of the latter are unquestionably less than those of forcible version against resistance than can be removed in no other way. As in all obstetric operations, the question whether the anesthetic be administered by a trained anesthetist or by one reasonably experienced is of less importance than that of willingness or unwillingness of the assistant to bring about as deep anesthesia as the procedure calls for.

4 Digital dilatation of the vulvo vaginal outlet is begun as soon as the patient is draped, and it is carried up to the point where the operator can insert his cone-shaped hand without perineal laceration. But dilatation should not be carried too far. On one hand, undesirable over-stretching with more or less permanent loss of vaginal and pelvic floor tone may result, and, on the other, delivery of the aftercoming head can be so conducted that all but minor degrees of perineal injury are prevented.

5 The cervix is examined to determine dilatation of the external os and the degree of obliteration of the internal. Its thickness and the presence of lower segment tone are determined by palpation. In the presence of even slight muscle-tone, the region of the contraction ring must be explored for evidence of tonicity. It is only under deep, surgical anesthesia that the contraction-ring fades out and complete, digital dilatation can be brought about. Version should not be attempted until the loosely-clenched fist can be brought through the lower segment and cervix with ease. As wide dilatation makes it possible for the position to be determined with absolute certainty.

6 The presenting part is immobilized, if necessary by counter-pressure above the symphysis, and the membranes are ruptured artificially. Even light engagement brings about a relatively slow escape of liquor amni and lessens the dangers of cord prolapse. The alternative procedure, namely, rupture of the membranes high up and the practice of version while the fluid is escaping, would seem to increase the hazards of cord accidents without proportionately adding to the ease with which version can be done.

7 The head is grasped by the "uterine" hand, and displaced upward and toward an iliac fossa—the right in right positions for instance. This maneuver helps in turning the child and is of immeasurable value as a test of complete uterine relaxation that must obtain before version may be attempted. If resistance is met, the presence of retraction is probable, and deeper anesthesia must be secured before a further attempt is made. The head that should be raised easily is held displaced while the "outside" hand, over the fundus, directs the feet toward the inlet where they are met by the "inside" hand. The latter grasps the child's feet between its first and second and third

fingers, the external hand now being used to hold the head in an iliac fossa. Version is completed by a combination of downward traction on the feet and upward pressure on the head exerted by the abdominal hand.

The feet should be made to advance toes-downward in order to favor advance of the back (and occiput) toward the front. At this point, the administration of ether is discontinued. Traction is persisted in until the knees appear at the vulva, when version is complete.

Use of the outside hand in the manner described facilitates version and at the same time lessens the extent of intra-uterine advance of the other hand, and its advantages in version at full-term are apparent. In premature labor, the aid is unnecessary. One or both legs may remain high in spite of outside pressure upon them, and to grasp them the uterine hand may have to be carried upward to the fundus. Both feet are to be brought down. Traction on a single foot doubles the risk of injury to ankle and hip, increases the difficulties of keeping the child's back toward the front, and makes it possible for the other leg to assume positions that may actually interfere with version. The "half breech" is efficient, even if unsafe, as a dilator, but it has no place in internal podalic version.

The position of the arms is disregarded. Since the head is kept flexed, the arms may be assumed to maintain their physiological position of general flexion. "Extended arms" is secondary to advance and does not occur until the shoulder girdle reaches the lower segment and pelvic inlet in the course of extraction. A prolapsed arm should be replaced and disregarded. Such treatment is far less hazardous than the application of a sling to the wrist for the purpose of preventing or of treating possible extension met at extraction. The ultimate position of a replaced arm is problematical, and dislocation or fracture might readily result from forcible downward traction upon it.

With the completion of version, the fetal heart must be auscultated to determine its rate and regularity. Rates below 100 and above 160 are indicative of developing intra-uterine asphyxia. The double-foot presentation may now be left to nature and a spontaneous delivery, or breech extraction may be done. Expectancy is permissible in the presence of normal fetal-heart sounds and returning uterine contractile efforts. Extraction is imperative in the presence of approaching asphyxia. It is desirable in the overwhelming majority of cases because, on the one hand, the operator has perfect control over the advance and delivery of the child and, on the other, spontaneous advance may be indefinitely postponed as a result of artificial inertia that the anesthetic is responsible for.

It is imperative that there be no uterine ob-

stacle to the relatively rapid advance that breech extraction calls for, and much of its attendant fetal mortality is believed to be due to the wholly avoidable difficulties met when breech extraction is attempted through a cervix just short of complete dilatation and through a lower segment presenting even slight retraction or tone. In the presence of uterine resistance of the kind, deep ether anesthesia is again secured, and complete uterine-muscle relaxation awaited.

It follows that extraction following version will commonly be done without the aid of efficient, expulsive contractions, and loss of such a desirable, supplementary force must be compensated for. Diffuse, fundal pressure must be depended upon to take its place.

If the cervix is found to be completely dilated and the lower segment thinned-out and drawn upward, the return of uterine contractions may be awaited before delivering the breech. If the child was in good condition at the completion of version, there is no necessity for haste, because the danger of cord pressure is negligible, and maximum expulsive efforts plus firm, fundal pressure are most important factors in producing uneventful advance because they help to keep the head well flexed and the arms, therefore, in place across the chest.

8 With the assistance of the forces just referred to, the breech should be delivered with relative ease. Resistance to advance means returning lower segment retraction or presence of the cord between the thighs, and the latter is so common following internal podalic version and the consequences of disregarding it are so serious that one may not proceed with extraction without satisfying oneself by palpation (if the buttocks are not yet in sight) that the child is not astride the cord. Immediately clamping and cutting of the misplaced cord make advance possible and eliminate the dangers of evulsion or placental separation that are possible consequences of attempts at "pulling down a loop of cord and delivering one leg through it."

Following delivery of the legs and the breech, a towel wrung from an antiseptic solution is wrapped about them. Hot towels about the body as it is born serve three purposes: first, they keep surface of the child's body warm and prevent premature inspiratory efforts that the relatively low room temperatures invite; second, they increase the efficiency of the operator's grasp on the child and, therefore, make it possible to decrease firmness of it, and, third, they lessen the dangers of contamination of the operator's hands.

The back should be kept toward the front to obviate the highly undesirable delivery of the after-coming head occiput-to-the-rear, and all that is required to secure such advance is to make the legs advance toes downward. The breech naturally advances sacrum-to-the right or to-the-left because the shoulder girdle engages and de-

scends through an oblique diameter of the inlet.

9 The most satisfactory advance from breech to angles of the scapulæ is that brought about by an excess of propulsive force from above over tractile force from below. The former tends to keep head and arms flexed and facilitates their later delivery, while traction from below favors extension of the head that allows the arms to become extended when lower-segment and pelvic resistances are met. Any deficiency in expulsive efforts due to inertia, either spontaneous or that produced by anesthesia, must be compensated for by increase in the amount of diffuse, downward pressure exerted upon the fundus. With no trained assistant available, the operator may well employ both hands in making pressure at the fundus after providing for momentary support of the child's legs and the breech. The soft, compressible lower body offers little resistance to advance, and progress from breech to scapulæ may be relatively rapid.

The moment of appearance of the navel must be noted. At this time circulation through the cord may be presumed to be completely shut off and oxygen is denied the child until air can reach it through the mouth. It follows that progress from navel to mouth must be relatively rapid, and, while the rule is not an arbitrary one, no more than four minutes should transpire before free passage of air to the child's mouth is provided for. This means that the mouth must reach the outlet or that air be conveyed to it by means of forcible depression of the perineum. A long, posterior, vaginal retractor serves the double purpose of keeping blood and other fluids away from the mouth and allowing air to enter it, and it should be ready for immediate use.

Because of the danger of intra-uterine asphyxia, extraction may not be conducted with too great deliberation, although the four-minute interval may be reasonably prolonged when the operator knows that the fetal-heart action was strong and regular and neither too rapid nor too slow when extraction was begun. For reasons that are apparent, the child born by elective version and extraction may manifest only slight asphyxia when the mouth is born as many as eight or nine minutes after the appearance of the navel, while the child born after repeated and ineffectual attempts at delivery by forceps may be so deeply asphyxiated within three minutes following the appearance of the navel that it cannot be revived. On the other hand, one is not justified in forcible and therefore more or less precipitous completion of breech extraction simply because the interval referred to has transpired and the head is still high. At such times, the danger of fetal injuries under heroic treatment is far greater than that of intra-uterine asphyxia under extraction completed with extreme care and without undue haste.

Potter emphasizes the necessity for being

"deliberate, careful and above all gentle in every step of the operation", and the general excellence of his results is due in part at least to the application of this principle. However, undue delay is no more permissible than undue haste, and that neither mistake be made it is advisable that each in minute following the appearance of the cord be called off by one previously designated to watch for it

After delivery of the breech and until the shoulders are born, the general direction of the child's body is downward and forward. It is supported by either forearm, when the palm of the hand can be brought in contact with the child's chest for purposes of palpating the heart beat

10 With the appearance of the angles of the scapulæ, the presence of the relatively broad shoulder girdle in the pelvic cavity retards advance. At this point it is imperative that spontaneous expulsive efforts or downward fundal pressures be exerted in order that the head and arms may be kept flexed against the lower uterine segment and the pelvic resistances that tend to extend them. Because excess of tractive force from below against the resistances mentioned results in extension of head and arms, the shoulder girdle should not be forcibly drawn into the inlet

The arms are found in one of three positions. First, they are folded across the chest with elbows just within the vulvovaginal outlet. Second, they are moderately extended at the shoulder and moderately flexed at the elbow. Third, they are completely extended and lie straight alongside of the head. The first is the natural position, met where expulsive efforts are highly efficient and where there is a minimum of maternal soft-part resistance. Delivery of the arms is readily accomplished by supporting the child's body, by inserting a finger just within the vagina, and by exerting traction on the wrists. Arms in the second position are partially extended, the attitude being accounted for by advance of the shoulders against the natural uterine and pelvic resistances. Uterine-muscle resistance is characterized as "natural" because it is presumed that pathological resistance due to retraction has been removed before delivery of the shoulders is attempted. But, while pelvic resistance cannot be eliminated, it can be utilized to excellent advantage in correcting the very abnormality it is in part responsible for

One or the other shoulder is commonly anterior. Because of the descent of the shoulder girdle is an oblique diameter, the back is rarely found directly to the front, but, if so found, the body should be rotated slightly until one or the other shoulder is anterior. The anterior arm is delivered in the following manner: the shoulder is rotated backward by digital pressure against it from the front supplemented by gentle turning

of the body, the elbow and arm, momentarily retarded by pelvic resistance, are directed obliquely downward and forward across the chest as the shoulder recedes and the moderately extended extremity begins spontaneous reduction as the elbow approaches the outlet, traction is now applied at the elbow, and the flexed arm, directed downward, forward, and inward, escapes beneath the symphysis. Delivery of the second arm is accomplished in the following manner: the upper chest and shoulder girdle are grasped firmly and rotated until the scapula of the momentarily posterior arm is brought under the symphysis (the direction of rotation being opposite to that practised in delivery of the first arm), and the extent of the rotation is such that the elbow is almost invariably found just within the vulvovaginal outlet, from which location it is readily delivered by applying traction at the elbow. If one has succeeded in rotating the body sufficiently, it is inconceivable that the arm remain even moderately extended, and for this reason its delivery is never difficult.

With arms in the third position, namely completely extended, advance is obstructed because the head and arms over-fill the pelvic inlet. In management, the initial step is to cease all tractive efforts on the breech and to discontinue downward pressure at the fundus. The arms are then delivered as in the previous position, although rotation of the shoulder girdle is supplemented by digital pressure exerted at the elbow in such a way that the joint is directed obliquely downward and forward in the direction of the opposite shoulder.

With arms presenting any degree of extension, each is delivered beneath the pubic arch because such management lessens the dangers of perineal laceration and contamination of the operator's hand. When an attempt is made to deliver the extended posterior arm first, the greater part of a hand must be introduced into the vagina. This almost invariably results in otherwise avoidable perineal injury, while the member is brought into such intimate contact with the anus that contamination is probable.

11 With delivery of the arms, the neck is inspected for the presence of loops of cord about it. If these are found, the cord is promptly clamped and cut. But of greater clinical importance is palpation of the anterior lip of the cervix. The latter structure together with the lower segment not infrequently manifests some tone, especially after vigorous efforts at delivery of the arms, which offers resistance to the advance of the head. The cervix appropriates the space between occiput and shoulders, and its grasp may be firm.

The head is made to engage by exerting traction on the child as it lies astride the operator's arm. Cervical resistance is most effectively removed by exerting upward digital pressure

against the rim of the cervix in the attempt to make the latter advance upward behind the symphysis and over the occiput as the head is held firmly against it. Following removal of the cervix as a possible barrier to advance, the child's body is raised in the general direction of the maternal abdomen and supported by an assistant who grasps it through a sterile towel. The advantages of this procedure will be considered presently.

12 The advance and delivery of the head are accomplished almost entirely through the employment of artificial forces. By this time the head is in the inactive, lower segment and practically no expulsive efforts are brought to bear upon it. Available forces are, first, fundal pressure, second, traction on the lower jaw, and, third, traction on forceps, and each has its advantages as well as limitations.

The dangers of the first and second, namely cerebral and lower jaw injuries, are minimized and satisfactory advance occasioned in the majority of cases as fundal pressure and traction exerted by one or two fingers in the mouth are applied gently but firmly and in approximately equal amounts. On occasion, however, the disproportion between head and pelvis amounts to enough to retard advance and to make delivery possible only through the employment of undesirable force at each point. Here, utilization of the third force, namely cephalic application of forceps, eliminates the dangers of localized pressures and assures delivery that is prompt but not precipitous. The application of forceps gives the operator quite complete control not only over the rapidity but also over the direction of the advance of the after-coming head, and it is indicated whenever the condition of the child demands prompt delivery. For use on the after-coming head, the advantages of the thin and solid blade forceps are apparent.

The head is born by ever-increasing flexion as the occiput is retarded at the symphysis and the sinciput travels the relatively long posterior border of the pelvic cavity, and it is to assure delivery of the head in perfect flexion that the child's body is placed with back toward the maternal abdomen. The body does not rest on the abdomen. As marked hyperextension might result in cervical injury, although even more extreme extension is met in presentation by the face, and "broken neck" in cases of the kind is not even a conventional complication.

With the child's body in the position mentioned haste in delivery of the after-coming head is rarely indicated because, with the mouth no lower than the low-mid-pelvis, air can be conveyed to it by inserting a posterior vaginal retractor. Further, quite perfect perineal control can be exercised and perineal injuries, accordingly, reduced to the minimum. As a matter of fact with due allowance made for deficiencies in moulding after-coming heads should occasion no more

perineal damage at delivery than fore-coming heads.

Delivery of the head by downward and forward traction on the shoulders, exerted by the first and middle fingers of the operator's "strong" hand, is never justified. Injuries to the cervical vertebrae, to the brachial plexus, and to the clavicles are invited when strong tractile efforts are required, and extensive perineal injury is inevitable if delivery of the head is precipitous. Under the circumstances, one is unable to flex the head or, better, to hyperextend the body upon it as rapidly as the passage of the head through the vulvovaginal outlet calls for, and the chin is accordingly directed through rather than over the perineal body. Non-physiological mechanism of delivery of the after-coming head is unquestionably the most important factor in production of the extensive perineal lacerations so common in delivery by the breech.

With the mouth at the outlet, the perineal stage is arrived at, and, in order that laceration may be minimized, it is desirable that the head be delivered slowly. The body of the child is held upright, blood and mucus are removed from the mouth by sponging, and the heart beat is carefully noted. The only indication for haste in delivery is asphyxia pallida with slow and weak heart action, and the only reason for clamping and cutting the cord early rather than late is to be able to place the child at once in a hot tub. The latter should be made ready as extraction is begun, moist heat being the most efficient and available fetal-heart stimulant.

Reference has already been made to valuable contributions to the technique of version and extraction made within recent years by Potter, and of them there are several that are worthy of especial emphasis. They are the modified Walker position, complete anesthesia preliminary to version, traction on both legs, rotation of the body so that each arm can be delivered "anteriorly," and, lastly, the importance of deliberation as each step of the procedures is gone through with. They have been considered in detail, and their advantages, if not apparent at once, will be appreciated as soon as a fair trial is given them.

Internal podalic version and breech extraction without asphyxia of a degree calling for treatment, and without injury to the child's extremities or to the maternal soft parts, is one of the most satisfactory experiences in operative obstetrics, especially so if the child is full-term and the mother a primipara, and experiences of the kind come not because of mere dexterity in carrying out certain maneuvers that some one else has carefully recorded, but rather because the operator makes proper choice of cases for vaginal delivery in the first place, knows the mechanism of labor in the second, recognizes abnormalities in it early rather than late in the third place and lastly possesses reasonable skill in applying mechanical principles to meet mechanical defects.

PYLORIC OBSTRUCTION IN INFANCY *

THEW WRIGHT, M.D., F.A.C.S

BUFFALO, N. Y.

ALTHOUGH the literature of the past ten years is replete with articles on the subject of pyloric stenosis in infants and the symptomology and diagnosis have been clearly set forth and the medical and surgical treatment ably discussed, its importance and frequency are still unappreciated by a large percentage of the profession. There are still too many infants buried with the diagnosis of marasmus or inanition and the subject should be repeatedly discussed, until the clinical picture and appropriate treatment are as familiar to the general practitioner as are those of appendicitis, for lack of recognition is quite as disastrous while prompt and proper treatment is fully as efficient.

Careful observations have placed the incidence as 1 in 200 (Hill)¹ and yet many practitioners have told me that they had never seen a case in twenty or thirty years of practice.

Apart from the relatively rare cases due to peritoneal bands causing obstruction of the pylorus or duodenum, pyloric obstruction in infancy is due to a combination of two conditions which are always associated but whose relative importance in the production of symptoms varies with the individual case, namely, pylorospasm and hypertrophy of the pyloric muscle.

Much confusion has resulted from the attempt to sharply differentiate these two and make two distinct types of cases, the purely spasmodic and the congenital hypertrophic.

My observations have led me to agree fully with Holt who believed that such a division is not permissible and that the congenital hypertrophy is the essential underlying factor in all these cases, the spasm being an added secondary condition. In some cases the spasmodic factor greatly outweighs the hypertrophic and in others the reverse is true.

Although an accurate differentiation between these two conditions might at first thought appear essential practically it is not so, for the stenosis may be as complete in one condition as in the other and the early treatment is the same and if it is not promptly successful, the later treatment is likewise identical for the two conditions.

In persistent stenosis due principally to pylorospasm there is always a slight hypertrophy of the pyloric muscle, but not enough to produce a distinctly palpable tumor.

In the second type there is actual hyperplasia of the circular muscle of the pylorus

often reaching four to five times the normal thickness.

There has been much discussion as to whether the hypertrophy is a pre or post natal affair. The weight of evidence is in favor of its being congenital, for cases have been found in premature stillborn infants. That the hyperplasia continues after birth is also most likely, for there is a striking uniformity in the reports that the actual size of the pyloric tumor corresponds to the age of the child. Some writers have held that the hypertrophy was due to spasm and hence acquired, an hypothesis which fails of appeal to one who remembers his youthful efforts to cause hypertrophy of his biceps.

The importance of spasm in the hypertrophic cases is in the production of symptoms through completing the stenosis. The presence of hypertrophy of the pyloric muscle even to a degree sufficient to produce a readily palpable tumor does not of itself mean stenosis and symptoms, as is proven by the persistence of such a tumor for weeks after the cessation of symptoms in cases successfully treated medically (Holt⁶).

It is not my purpose to discuss etiology. Many theories have been advanced and are covered in the writing of Holt⁶, Scudder¹¹, Downs³, Richter¹², Stiles¹³, La Fetra¹, Pfandler² and others.

The clinical picture of pyloric stenosis is so typical that it is only the exceptional case that will be confusing. An apparently healthy normal infant begins, usually during the second to fourth weeks of life, to vomit its feedings. The fact that most infants of this age are still nursing explains the often repeated observation that the majority suffering from this condition are breast fed. The vomiting increases in frequency and soon assumes the projectile type. In advanced cases the vomitus may be propelled four to five feet. Vomiting may occur shortly after each feeding or may be postponed until after several feedings they are ejected at the same time. There is always gastric retention, i. e. but little if any food passes the pylorus. With the persistence of vomiting the stools become less frequent, until milk stools are absent and nothing but mucus or small meconium-like stools are passed. The urine becomes scanty and concentrated, for the infant vomits water as well as milk and rapidly becomes dehydrated.

Soon after vomiting has become well marked visible gastric peristalsis appears, which together with projectile vomiting is absolutely diagnostic. The peristaltic wave starts under the left costal margin and travels downward

* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse, May 13, 1925.

to the right and across the median line to disappear in the right hypochondrium. In a well marked case it is by no means uncommon to see two waves at once and for them to be $\frac{1}{2}$ to $\frac{3}{4}$ of an inch in height. They usually follow promptly the ingestion of food or water and persist intermittently until the child vomits, with an explosion that projects the vomitus several feet.

If these symptoms have existed for some days or weeks all the signs of inanition are present, wrinkled face and skin, dry tongue, sunken eyes, etc. Such a picture may be produced by marked spasm with slight hypertrophy or by true hypertrophic stenosis. In the latter case palpation after the stomach has been emptied either by vomiting or tube will in the vast majority of cases reveal an olive shaped tumor at the site of the pylorus. The tumor can best be palpated by using the left hand and from the patient's left side. Downes states that the tumor is palpable in practically every case. This is doubtless true if sufficient care and time are given to its finding. Not considering the demonstration of the tumor essential in all cases I have operated upon several in which I had failed to palpate the tumor, although it was well marked. Occasionally a large right lobe of the liver will render palpation difficult.

Before the advent of the Rammstedt operation surgical interference in cases of pyloric stenosis was accompanied by so high a mortality that it was justly reserved for cases of true marked hyperplasia and more importance was attached to the actual palpation of the tumor than is, in my opinion, called for today. An emaciated, dehydrated babe with projectile vomiting and marked visible gastric peristalsis and a history such as I have mentioned is suffering from pyloric stenosis and requires prompt relief. If that relief cannot be quickly brought about by medical treatment it should be given the benefit of surgery without delay, for it will be just as dead from persistent spasmodic obstruction without true hypertrophy enough to give a readily palpable tumor, as though the tumor were as big as one's thumb. With an operation so simple as the Rammstedt and with so little risk, I have no hesitancy in advising its performance even in cases that I feel are 90 per cent spasm. We can be confident of prompt and permanent relief and in a few hours have a babe that is taking its full quota of food. I know nothing more striking or even spectacular than the contrast between the contented baby quietly assimilating its food on the day following operation and the wretched, starved child of the previous twenty-four hours, with its big eyes and wistful expression, lest it be

the change wrought in the exsanguinated child by a well timed blood transfusion.

Approximately 1-3 of the cases I have operated upon have been cases of spasm with some hypertrophy, though not enough to give an easily palpable tumor. Not one of the cases has died and each has made a rapid convalescence and completely justified the operation. Several of these were in as extreme a condition of starvation as any of those with a marked hyperplastic pylorus. Hill⁶ in his series of cases noted practically the same proportion of pylorospasm and true hypertrophy.

The diagnosis of hypertrophic stenosis should but rarely present any difficulty. First of all the age of onset should direct attention to its possibility, this in nearly all cases falling within the second and sixth week of life.

The diagnostic points in order of their importance are

- 1 History of increasingly progressive vomiting of projectile type
- 2 Marked visible peristalsis
- 3 Abnormal gastric retention
- 4 Wasting, constipation, scanty urine
- 5 Palpable tumor

Although some observers, notably Strauss, place importance upon X-ray study, I feel it to be unnecessary and often an unjustifiable procedure. It certainly is unnecessary for the diagnosis of obstruction and may in extreme cases be a fatal procedure either through its severity or through delaying operation.

Strauss¹⁰ claims that by X-ray study he can differentiate between those cases requiring surgery and those which will recover under medical treatment. I contend that in many cases that might recover under prolonged medical treatment surgery is much more prompt and surely efficient and in the type of case that promises well under medical treatment causes practically no mortality. That instead of weeks of careful feeding and nursing during which the patient's condition may at any time suddenly become desperate or death may occur surgery offers a prompt and efficient means of cure. Within a week the baby is nursing and retaining all its food as a normal child, and it is permanently cured with no danger of the relapses that are so common following successful medical treatment. I do not mean that every babe presenting symptoms of pyloric stenosis should be operated upon immediately. If the condition is recognized shortly after the onset of symptoms medical treatment should be tried. All degrees of stenosis are met with and many mild cases, if properly handled, will be successfully treated without recourse to surgery.

Many cases in which the spasmodic factor is the predominating one respond promptly to

atropin, gastric lavage and careful feeding Others to the thick farina feedings The more severe cases can only be successfully handled medically when the most expert nursing is available Remarkable results have been accomplished in some cases by the thick feeding method (Porter¹⁰, Sauer¹³) but its proper application is complicated and time consuming and relapses occur

Cases that are seen early may properly be treated medically for a week to ten days provided they show a slight steady gain If, however, they remain stationary in weight or lose slightly during this time I believe they should be operated upon

Cases that are first seen in the later stages should I believe be operated upon without delay Hypertrophic pyloric stenosis is as definitely a mechanical obstruction as any other type of gastro-intestinal obstruction and should be so considered and it should be recognized that its mortality is as elsewhere a mortality of delay

The following observations of Goldbloom and Spence⁴ made upon a large series of cases at the New York Babies Hospital show this point most clearly

1 The duration of symptoms prior to operation is probably the most important single factor affecting the prognosis When symptoms have lasted less than four weeks, the mortality is one third as great as when they have lasted four weeks or longer

2 The mortality in artificially fed babies is more than three times that for breast fed babies

3 In infants weighing 7 pounds or less, the mortality was three and one-half times as great as in those who weighed more than 7 pounds

4 The mortality for breast fed infants who vomited less than four weeks and who had lost less than 20 percent of their best weight is almost nil The fatalities which occur are due to accidents unusually avoidable when the operation is done by a skillful surgeon"

Holt⁶ places the mortality of the condition under medical treatment at 58%

Surgical treatment Of all the procedures that have been tried for the surgical relief of this condition the Fredet-Rammstedt is in my opinion the operation of choice

Gastro-enterostomy is difficult, unnecessary and although efficient, leaves an abnormal situation, is attended by a high mortality rate and has been properly abandoned The more complicated methods of pyloroplasty are unnecessary as they are no more efficient in relieving the obstruction than a well performed Rammstedt

My experience in operating for this condition is limited to 75 cases of which the first five were pyloroplastics according to the method of Nicoll, all of which recovered My sixth case early in

1914 was so nearly moribund at the time of operation that after cutting the muscle as the preliminary step of the Nicoll operation both my anesthesiologist and I felt that further operation would be promptly fatal I therefore merely separated the cut muscle and closed the abdomen expecting the baby to die To my surprise he made a rapid convalescence and is today a healthy vigorous child Shortly after this the Rammstedt¹¹ operation came to my attention and since that time I have performed it exclusively

I have lost four babies Three of the cases were apparently moribund at the time of operation and died within the first twelve hours, though there were others in the series who appeared in as desperate a condition who made good recoveries The fourth was a case in apparently fair condition, which died suddenly three hours after operation This case was operated upon under ether and we felt the death was possibly thymic but as autopsy was denied the exact cause of death is unknown Several of the cases were in an extreme marasmic state and were brought to operation as last resort

The series does not represent selected cases and no thought was given to statistics Three of the cases that died might have been denied operation without criticism but for the recovery of at least two previous infants whose condition had been adjudged hopeless by my colleagues and myself prior to operation

Since the death of the third child I have used local anesthesia in all cases, feeling that the elimination of inhalation anesthesia lessened the risk although I have made the observation that occasionally ether seems to have a somewhat stimulating effect.

I grant that infants stand ether anesthesia well but I also feel that ether or chloroform introduces an added risk to child or adult and agree with Bevan that this operation should always be performed under local anesthesia if possible

I have found that it can usually be readily performed under 1/2% novocaine although in certain cases I have used a small amount of ether for a few moments if there was any tendency for the intestines to protrude into the wound Fortunately the sicker and younger the child the more easy the performance under local The two important points in successful use of local anesthesia namely, the allowance of sufficient time for the anesthesia to occur and gentleness in handling the tissues apply here as in adults and one who is accustomed to the use of local in adult surgery will have little difficulty in working with it here

The operation is simple but there are a few technical points that should be borne in mind,

First Immediately before operation the stomach should be thoroughly lavaged with one percent soda bicarbonate solution This might

to the right and across the median line to disappear in the right hypochondrium. In a well marked case it is by no means uncommon to see two waves at once and for them to be $\frac{1}{2}$ to $\frac{3}{4}$ of an inch in height. They usually follow promptly the ingestion of food or water and persist intermittently until the child vomits, with an explosion that projects the vomitus several feet.

If these symptoms have existed for some days or weeks all the signs of inanition are present, wrinkled face and skin, dry tongue, sunken eyes, etc. Such a picture may be produced by marked spasm with slight hypertrophy or by true hypertrophic stenosis. In the latter case palpation after the stomach has been emptied either by vomiting or tube will in the vast majority of cases reveal an olive shaped tumor at the site of the pylorus. The tumor can best be palpated by using the left hand and from the patient's left side. Downes states that the tumor is palpable in practically every case. This is doubtless true if sufficient care and time are given to its finding. Not considering the demonstration of the tumor essential in all cases I have operated upon several in which I had failed to palpate the tumor, although it was well marked. Occasionally a large right lobe of the liver will render palpation difficult.

Before the advent of the Rammstedt operation surgical interference in cases of pyloric stenosis was accompanied by so high a mortality that it was justly reserved for cases of true marked hyperplasia and more importance was attached to the actual palpation of the tumor than is, in my opinion, called for today. An emaciated, dehydrated babe with projectile vomiting and marked visible gastric peristalsis and a history such as I have mentioned is suffering from pyloric stenosis and requires prompt relief. If that relief cannot be quickly brought about by medical treatment it should be given the benefit of surgery without delay, for it will be just as dead from persistent spasmodic obstruction without true hypertrophy enough to give a readily palpable tumor, as though the tumor were as big as one's thumb. With an operation so simple as the Rammstedt and with so little risk, I have no hesitancy in advising its performance even in cases that I feel are 90 per cent spasm. We can be confident of prompt and permanent relief and in a few hours have a babe that is taking its full quota of food. I know nothing more striking or even spectacular than the contrast between the contented baby quietly assimilating its food on the day following operation and the wretched, starved child of the previous twenty-four hours, with its big eyes and wistful expression, lest it be

the change wrought in the exsanguinated child by a well timed blood transfusion.

Approximately 1-3 of the cases I have operated upon have been cases of spasm with some hypertrophy, though not enough to give an easily palpable tumor. Not one of the cases has died and each has made a rapid convalescence and completely justified the operation. Several of these were in as extreme a condition of starvation as any of those with a marked hyperplastic pylorus. Hill⁸ in his series of cases noted practically the same proportion of pylorospasm and true hypertrophy.

The diagnosis of hypertrophic stenosis should but rarely present any difficulty. First of all the age of onset should direct attention to its possibility, this in nearly all cases falling within the second and sixth week of life.

The diagnostic points in order of their importance are

- 1 History of increasingly progressive vomiting of projectile type
- 2 Marked visible peristalsis
- 3 Abnormal gastric retention
- 4 Wasting, constipation, scanty urine
- 5 Palpable tumor

Although some observers, notably Strauss, place importance upon X-ray study, I feel it to be unnecessary and often an unjustifiable procedure. It certainly is unnecessary for the diagnosis of obstruction and may in extreme cases be a fatal procedure either through its severity or through delaying operation.

Strauss¹⁰ claims that by X-ray study he can differentiate between those cases requiring surgery and those which will recover under medical treatment. I contend that in many cases that might recover under prolonged medical treatment surgery is much more prompt and surely efficient and in the type of case that promises well under medical treatment causes practically no mortality. That instead of weeks of careful feeding and nursing during which the patient's condition may at any time suddenly become desperate or death may occur surgery offers a prompt and efficient means of cure. Within a week the baby is nursing and retaining all its food as a normal child, and it is permanently cured with no danger of the relapses that are so common following successful medical treatment. I do not mean that every babe presenting symptoms of pyloric stenosis should be operated upon immediately. If the condition is recognized shortly after the onset of symptoms medical treatment should be tried. All degrees of stenosis are met with and many mild cases, if properly handled, will be successfully treated without recourse to surgery.

Many cases in which the spasmodic factor is the predominating one respond promptly to

the starved patient's tissues possess an abnormal digestive power I do not know, but similar observations have been made by others

The post operative treatment of these cases is of extreme importance. It must be remembered that the child is primarily suffering from starvation and that the indication is to supply food and drink as quickly as possible. One distinct advantage of local anesthesia is that it permits of much earlier feeding.

One half ounce of water is given one-half hour after operation. If retained, as is usually the case, breast milk one-half ounce, if obtainable, is given one hour later. It is of great advantage to have breast milk, but if none is available either milk or a formula the skim milk, barley water and sugar may be used. The milk feeding is given every three hours, increasing by 2 C C at each feeding. Midway between feedings water is given in equal quantity. The feedings are thus gradually increased until the average case at the end of twenty-four hours the child is taking an ounce at a time. The advanced cases are always dehydrated and it is often wise to supplement the water intake by hypodermoclysis. Proctoclysis is rarely of use. If possible the child is put to the breast one week after operation and nursing supervised so that not more than 2 ounces are taken at a feeding during the second week. Thereafter the child may take its fill and can in the vast majority of cases be treated as a normal child.

We meet, of course, with difficult feeding cases after a Rammstedt operation as well as in infants who have had no pyloric stenosis and they are handled in exactly the same manner as though there had been no surgical procedure.

It is the exception to have vomiting persist after operation. Many cases will regurgitate once or twice during the first twenty-four to forty-eight hours retaining, however, practically all their nourishment. If vomiting occurs and is at all marked it had been my experience that prompt gastric lavage and the semi-erect posture will stop it. A teaspoonful of castor oil twenty-four hours after operation will remove gas and mucus and aid in the establishment of normal intestinal action. The tendency to diarrhoea seen in the more advanced cases will usually respond to modification of the feedings.

The incision is left undisturbed for nine or ten days unless there is some indication for earlier inspection. At this time the retaining sutures are removed.

One case in this series was complicated by continuous and profuse oozing from the skin incision, although the child when a week old and eight weeks prior to operation had been

circumcised without showing any tendency to abnormal bleeding. The hemorrhage was sufficiently profuse to suggest the possibility that a small vessel in the abdominal wall might be its source. I therefore reopened the skin incision but no bleeding vessel was found. After resuturing the skin the hemorrhage persisted in spite of two subcutaneous injections of father's blood and one transfusion of the mother's. I therefore again opened the skin incision and packed it with Coagulen and sterile gauze after which bleeding ceased. Two days later I removed the gauze pack and strapped the skin and prompt healing took place.

Conclusions

- 1 Congenital pyloric stenosis is sufficiently common to deserve more general recognition.
- 2 Mild cases may be treated medically.
- 3 Severe cases and those not rapidly responding to medical treatment should receive prompt surgical treatment.
- 4 The simplest and best surgical treatment is the Rammstedt operation.
- 5 The advantages of local anesthesia are sufficient to make it the method of choice.
- 6 The mortality of congenital pyloric stenosis is the mortality of delay, the operation itself having practically none.

at first thought appear superfluous in a child that is constantly vomiting. It must be remembered, however, that the stomach is not completely emptied and one is often surprised to find the amount of stagnant gastric contents that will be withdrawn. Furthermore there is often a hypersecretion of thick tenaceous mucus in the stomach which if not removed may cause partial plugging of the pylorus during the first few hours after operation.

Second The infant should be kept thoroughly warm during operation as the only factor that can produce shock in the properly handled local anesthesia case is chilling from undue exposure.

Third An ordinary rubber nipple stuffed with cotton moistened with sugar solution should be in readiness. If this is given to the child as soon as the peritoneum is incised I have found that in nine cases out of ten the short intraperitoneal handling can be done with no evidence of discomfort and with perfect ease. I have done 51 of these operations under local anesthesia and since adopting this simple procedure have in forty of these cases used no ether at any stage of the operation nor have I had any evidence of imperfect anesthesia.

Fourth I find that the location of the abdominal incision is of importance. I make a high rectus incision in the outer third of the muscle. This is done so that the major portion of it is over the right lobe of the liver. The liver is readily held out of the way during the delivery of the pylorus and after the pylorotomy is done and the stomach replaced there is no difficulty in closing the peritoneum, as the liver makes an ideal natural spatula and there is no tendency for intestine or omentum to force its way into the line of suture, as when a lower or more mesial incision is made. I have not seen attention called to this point but have found it well worth observing.

Fifth The pylorus is most easily delivered by means of a blunt hook as advised by Strauss.¹⁶ The pyloric end of the stomach often bulges into the incision but it is thick and difficult to grasp so that time is saved by gently hooking it up.

Sixth The pylorus and adjacent portion of stomach and duodenum should be delivered through the incision and held in the thumb and forefinger of the left hand.

Seventh At the junction of upper and middle third of the anterior surface of the pylorus, which is at its least vascular part, a longitudinal incision is made beginning at the duodenum and extending well into the prepyloric portion of the stomach. This incision should be most superficial, scarcely more than a millimeter in depth. Through this and with the blunt end of the scalpel the entire thickness of the pyloric muscle should be split until the mucosa is clearly seen throughout the entire length of the pylorus. The mucosa should

then be gently separated from the overlying muscle on both sides of the incision until it herniates well above the peritoneal level. This is accomplished by stretching the muscle wound with a blunt hemostat and shelling the mucosa away from the inner surface of the muscle with the handle of the scalpel. The efficiency of the operation in the markedly hypertrophic cases depends upon the thoroughness with which this step is carried out. Many observers have called attention to the danger of opening the duodenal mucosa unless great care is exercised in handling that end of the incision. The duodenum is very thin at its beginning and the change from hypertrophied pylorus to thin duodenum is very abrupt. I can testify that the danger is a real one for while calling the attention of my students to the possibility of its occurrence and proceeding with great care I opened it myself. The accident need however cause little concern if noticed, for the pouting mucosa can be caught with a clip and a ligature will readily close the opening. A careful inspection should always be made for such a possible opening for if not repaired peritonitis might easily follow.

In the cases in which spasm is the main factor the pylorus is more vascular than in the marked hypertrophic cases. In the latter type the pylorus is ischemic and there is practically no bleeding at all, in the former there may be considerable oozing. I have always found that this could be controlled by pressure of gauze wrung from hot water and have not as yet found occasion for the running suture over the cut muscle edge as suggested by Downes⁸ and Hill⁵.

This finishes the operation and the pylorus is returned to its place. There is no need to suture omentum over the pyloric incision nor is there in my opinion any necessity for a more complicated pyloroplasty.

Eighth The peritoneum and posterior sheath of the rectus is then repaired by a continuous catgut suture and just before tying the last stitch the peritoneal cavity is filled with warm saline.

Ninth Before closing the anterior rectus sheath three through and through silkworm sutures are passed extraperitoneally to be tied over a thin roll of gauze after the skin is sutured. This precaution I feel is necessary because of the fact that several cases have been reported in which the abdominal wound has opened, as it did in one of my earlier ones. In this case the wound separated on the third day and although chromic catgut had been used there was not a vestige of it to be seen. The gut was a commercially prepared gut of excellent quality and other samples of the same lot were tested and proved perfect. There was no infection in this case and after resuturing, the wound healed nicely and the child made a good recovery. Whether

license to practice midwifery When she submitted her first application, it was not regular as she stated that many of the cases which she presented—in lieu of a diploma—had been attended under the instruction of her late husband, and could not be signed as required, owing to the fact that he had died four years previously Upon the recommendation of the health officer, her first license was issued February 27, 1915 In 1915 she was visited by a nurse from the department. She was not co-operative from the first, and very reluctantly answered questions, openly resented the inspection and failed to show equipment or license The nurse reported her to be most erratic and really practicing as a physician She told the nurse that she was a Quaker minister, that she did no harm, that she only relieved the sufferings of humanity, and that no one could stop her She stated that she was an artist, author, music teacher and public speaker, and that she had graduated from several colleges In her home were large quantities of medicine and surgical instruments which, she said, were her late husband's

On June 28, 1915, Dr Williams, then Deputy Commissioner, wrote to Mrs S and advised her that a midwife's license gave her no authority to practice medicine, and asked her to accept the advice and warning

Nurses from this department visited Mrs S from time to time, and reported that she was said to be practising medicine, but there were no specific complaints filed The physicians, presumably on account of their loyalty to Dr S, were silent in regard to her actions, and it was reported that two of them protected her by signing death certificates of cases dying in her practice She had always taken cases in her home, when she so desired, and had held office hours three times a day, furnishing medicines for every ill In the absence of definite charges, Mrs S's license was renewed each year until toward the close of 1921, when she was reported by the health officer as having performed a circumcision The Commissioner thereupon directed that her license be withheld, and she was accordingly notified, but Mrs S did not stop her midwifery work nor her practice of medicine She has delivered more than 300 cases since her license has been taken away Until recently her late husband's sign has been in the window but she removed it about a year ago Her practice has not been confined to one city but extended throughout the county, and has included the following cases, as reported to the State Department of Health

1 Circumcision, followed by severe infection, which was later treated by the health officer

2 Diphtheria, diagnosed by her as "contagious sore throat," and so treated until too late for antitoxin and child died

3 Scarlet fever, diagnosed by her as "acid rash," and so treated until discovered and reported to health officer

4 Septicaemia, following childbirth, treated by her until too late and patient died

5 Syphilis, diagnosed and treated by her until discovered to be in a very communicable stage, and the patient removed from a restaurant

6 Measles, diagnosed and treated Board of Health placards house upon her recommendation without any further investigation

7 Failure to report birth of baby born dead, age between seventh and eighth month gestation, and baby buried without burial permit Mother treated for months and samples of medicine obtained

8 Heart disease and rupture—boy, seventeen years of age, treated and died in her home without medical attention

9 Heart disease—treating a 12-year-old girl, giving two kinds of tablets to build up heart muscle Child has been taking these tablets for four years

February 8, 1922—Commissioner referred case to Attorney General's office, because of her general defiance and specifically because of her treatment of a case of diphtheria in which the child died

May 31, 1922—Again appealed to Attorney General's office, for action on above case

June 30, 1922—Ruling requested from Attorney General's office re supplying Mrs S with birth certificates That office replied that they should not be supplied to her

March 3, 1923—Whole matter of her continued defiance again referred to the District Attorney's office by the health officer, specifically because of her treatment of a case of puerperal septicaemia in which patient died, also because of treatment of scarlet fever diagnosed by Mrs S as "acid rash"

March 1, 1924—Trial by jury, specifically for failure to report a stillbirth and for practising medicine

March 12, 1924—Again appealed to Attorney General's office, because of failure to indict in above case. Attorney General's office requested list of births reported by Mrs S since license was refused and list of over 100 cases was handed to that office

June 21, 1924—Affidavits on births reported, secured by Miss T given to Attorney General's office

November 5, 1924—Again appealed to Attorney General's office for advice re supplying

SOME INCONSISTENCIES IN THE PUBLIC HEALTH LAW AND THE DIFFICULTIES IN ADMINISTERING IT

MATTHIAS NICOLL, Jr, M D
ALBANY, N Y

This is neither a plea for greater official power or increased prerogatives, nor the expression of a desire to escape the performance of any duty, now imposed by law upon the Commissioner of Health of the State. I simply wish to bring before this Society and spread upon the record certain facts affecting the public health of the state, which should be something of an incentive to an effort to straighten out inconsistencies in the Public Health Law, and make that part of it which governs the practice of medicine and other professions really effective in protecting the public health against fraud and incompetence.

Article II, Section 4, of the Public Health Law, defines the general powers and duties of the Commissioner of Health, among them, he is charged with the enforcement of the Public Health Law and the Sanitary Code. Articles VIII, IX, X and XI, of the Public Health Law, relate solely to the practice of medicine, dentistry, veterinary medicine and surgery, and pharmacy, respectively. These articles prescribe the qualifications for the legal practice of the various professions, and set forth penalties for infractions of the Public Health Law, and of certain sections of the Penal Law. Whose duty it is to collect evidence and bring charges against law-breakers, is not designated, although under Section 174, Article VIII, incorporated medical societies or county medical societies are expected, by inference, to furnish such evidence since the law provides that any fines collected, as a result of the complaint of a medical society, shall be paid to the latter, in lieu of expenses incurred. The sections of the Public Health Law referred to are just as much a part of the whole law as those which relate to the control of infectious diseases or other obvious duties of a health officer, and yet I desire to point out that the State Commissioner of Health has, by administrative practice, absolutely nothing to do with carrying them out—that lies entirely in the hands of the Board of Regents and its agencies as, in my opinion, it should.

It is true that many complaints against unlicensed practitioners are received by the Commissioner of Health, and by local health officers referred to him. Such complaints have been, as a rule, in turn referred to the State Department of Education or directly to the local district attorney. I shall not be deemed guilty of betraying any secret when I tell you that, in the vast majority of instances, and for reasons, some of which I shall touch upon later,

the results have been negative in so far as legal indictments are concerned, although it is true that in many cases the community has been relieved of the activities of a charlatan who is certain, however, to appear in some other place.

The Commissioner of Health should always be willing to cooperate with other departments of government for the protection of the public health, but should be relieved of responsibility for carrying out the provisions of a law with which, by custom and practice, he has absolutely nothing to do. I shall be glad to have the cooperation of this Society in my purpose to have Articles VIII to XI, of the Public Health Law, transferred to the Education Law.

By Article VIII-A, the licensing and registration of midwives of the state, except in the City of New York, is placed under the authority of the State Commissioner of Health. Such authority has been sustained by the Supreme Court of the State. Under it, the Commissioner has taken over the supervision of more than 400 midwives in the 57 counties of the state, and has prescribed rules and regulations for the conduct of their work. As a rule, these women are doing their work conscientiously and effectively, and unquestionably meet the needs and wishes of certain classes of our population—especially the foreign-born. From time to time, it has been necessary to refuse the renewal of the license—which is given annually—or to deprive a midwife of a license. This never fails to bring about a legal battle, attempts to use personal and political influence and, in a number of instances, the surreptitious continuation of practice without a license. Occasionally, a midwife's license has been refused because she has been engaged in the practice of medicine or even surgery.

I think it may be of interest to this Society to cite two cases somewhat in detail which, while they involve principally the practice of midwifery, yet to my mind illustrate, very clearly, the weakness of the legal machinery available to bring about prosecution and conviction of offenders against the Medical Practice Act or the practice of midwifery.

The following summary has been made, for me, by the supervising nurse of the State Department of Health, who is directly in charge of the activities of midwives.

Mrs S, resident of a third-class city, first came to the attention of the department late in 1914, when she applied and was granted a

THE ANNUAL MEETING

The annual meeting of this Society will be held in the Waldorf-Astoria, New York City, on March 30th, 31st and April 1st. The scientific program, published in this issue, indicates that the sessions of the sections of the Society will be full of papers of unusual interest and justifies a record-breaking attendance.

On account of the very great success of the Thursday session on Tuberculosis last year in Syracuse, the Committee on Scientific Work wisely decided to test out at this meeting the same general plan and will present Syphilis from every point of view at that session.

It would seem wise in these days of specialism and near-specialism that the Medical Society of the State of New York, made up very largely of general practitioners, should conclude its annual meeting with a session in which the unity of the Society should be strikingly emphasized and the

necessity of a broad clinical viewpoint clearly demonstrated.

Osler said "I often tell my students that it is the only disease which they require to study thoroughly. Know Syphilis in all its manifestations and relations, and what remains to be learned will not stretch the pia mater of a megalocephalic senior student."

The Committee has therefore striven to present this subject—*Syphilis*—on Thursday, April 1st, in a way which will be most helpful to every member of the Society, no matter what his field of practice.

Such a demonstration—probably the most complete ever presented in this country—will repay manifold, even hundredfold, in knowledge and worth-while technique any expenditure of time and money by those fortunate and wise enough to attend. The halls of the Waldorf-Astoria should be crowded to the doors for this meeting.

Mrs S with silver nitrate and also concerning the slips of paper on which Mrs S submitted birth report data for the Registrar to copy

April 6, 1925—Whole case of her continued defiance again referred to Attorney General's office for action

August 24, 1925—Appealed to Attorney General's office for action and upon advice from that office, Miss T was sent for affidavited evidence, looking toward another trial

October 13, 1925—Affidavited evidence and facts in case presented to Grand Jury, specifically for practise of both midwifery and medicine without a license Failed to indict

On December 21, 1925, the Attorney General wrote the following information regarding this case

"I find that this case has been presented to grand juries at various times, which grand juries have failed to indict the defendant, either on the charge of practising medicine without a license or of practicing midwifery without a license

"From my conversations with the District Attorney and his two assistants, there seems to be a feeling among the people in the city of friendliness towards the defendant and her practice This feeling, of course, is reflected in the grand jury, and may have been one of the contributing factors in the failure of the various grand juries to indict her

"I am advised by the District Attorney and his assistants that the people she has attended are practically all friendly to her, and disinclined to say or do anything which may embarrass or injure her

"This matter was also tried out in the city court, which failed to convict her on the charge of practising midwifery without a license

"I am also advised that the witnesses subpoenaed before the grand jury maintain that she is capable and gives good services in her practice of midwifery I believe from my conversations with the District Attorney and his assistants that the people have not made out a case against her for practising medicine, but have made out a case against her in the practice of midwifery, but the grand juries seem to be loath to and do refuse to indict her"

The second case is somewhat more encouraging, though its satisfactory culmination has been reached through the expenditure of considerable money, time and effort

In 1922, a certain midwife's license was withheld because she had performed an abortion The patient gave all the information before witnesses—but on a promise that the statements would not be used, and no legal action could be taken Early in 1922, the midwife employed an attorney to force the Commissioner to issue a license to her, and a mandamus order was directed to the Commissioner to that effect The case was argued at the May term of the Supreme Court, Appellate Division, and the decision was handed down in the September term "emphatically sustaining the discretionary powers of the Commissioner to issue or withhold annual licenses to midwives as provided in the Public Health Law" Nevertheless, this woman continued to deliver cases and did not report the births Reports were received, from time to time, that she was performing abortions but such evidence was difficult to secure City court records disclose that the woman was convicted four times, once for violation of the Sanitary Code and three times for infractions of the Public Health Law On January 5, 1926, she was sentenced to one year in Auburn prison for performing an abortion This case illustrates very well the difficulties which are encountered and the time that is expended in order that a habitual offender against the Public Health and Penal Laws may be adequately and justly punished, and the community protected In this case, the final result was effected largely through the indefatigable work of the City Health Officer

I am aware that the State Medical Society will, at this session of the legislature, renew the effort to provide a working machinery for upholding the Medical Practice Act, and protecting the people of the State against fraud and charlatanism The facts that I have presented are by no means unique, but may be of some slight service in emphasizing the weakness of our present machinery in producing results of any real value or the unnecessary time and effort involved in achieving them

While Priestley analyzed gases and developed the modern art of chemical analysis, Lavoisier showed the composition of water and the nature of fire, and their relation to oxygen, and developed the foundation of the modern science of chemistry as distinguished from its art. It had long been known that when metals were heated in the air, they were calcined—that is oxidized, and that when the calcined product was heated with charcoal, the metal was recovered, and fixed air—carbon dioxide—was produced. The common interpretation of this phenomenon was that phlogiston was added to the metal during calcination, and was given back to the air when the metal was restored. But after Priestley discovered oxygen, Lavoisier gave out the modern theory that calcination was oxidation, and that when deoxidation occurred, the oxygen united with the charcoal and produced the fixed air.

The active investigations of Priestley extended through a period of over thirty years—a generation of time—and yet he clung to the phlogiston theory to the end of his days, although his own discoveries had supplied the principal material for its overthrow. But Priestley was a kindly man, and he entered into no controversy over the subject. It must be confessed that the facts so far as he knew them could be explained by the phlogiston theory, provided one could carry in mind the complicated modifications that were necessary in order to maintain it. However, the final acceptance of the modern theory required only the substitution of the word oxygen for phlogiston. It may be that Priestley's theological training influenced him to cling to the belief in

imaginary substance which no one could identify or weigh or measure.

Most of Priestley's chemical apparatus is preserved in the University of Pennsylvania and in the Smithsonian Institute in Washington. But many of his personal effects are in the possession of his kinfolds in Northumberland. There are his microscope with a single lens, microscope slides mounted in bone frames each containing a series of five or six preparations, and his telescope. A memento of peculiar interest is the magic lantern with colored slides, crude but artistic, and mostly scenes of home life, which were used for the entertainment of the children of the family at Christmas and other special days. The preservation of these mementoes speaks volumes for the beauty of his home life and the esteem in which he was held by his family. A few days before his death he wrote "Few persons, I believe, have enjoyed life more than I have done."

The centennial of Priestley's discovery of oxygen was celebrated on August 1, 1874, by a meeting of the Chemists of America in Northumberland. On the same day a statue of Priestley was unveiled in Birmingham, England, on which occasion Thomas Huxley said "If the nineteenth century is other and better than the eighteenth, it is in great measure to him and such men as he that we owe the change. If the twentieth is to be better than the nineteenth, it will be because there are men among us who walk in Priestley's footsteps. Such men are not those whom their own generation delight to honor; such men in fact rarely trouble themselves about honor, but their work will live as long as time endures."

MEDICAL SCHOOL ENDOWMENTS

Higher education is now largely diverted from its former object of supplying the spiritual needs of the people to that of ministering to them in their physical and mental abnormalities. But the change is not so great as it might seem. Pastors during Colonial days were much more than pulpit orators, they were the leaders of their communities in education, in science in business, and in statesmanship. They led the settlers to new fields, and they fanned the spark of independence in Revolutionary days. Many pastors were also physicians to their flocks, and most of them were practitioners of such applied psychology as was known in their day. Colleges were founded for the purpose of supplying pastors who were educated along all lines of science that were then known, and beneath their veneer of denominationalism the pastors had a broad knowledge which enabled them to guard against the quacks—medical, mental, and spiritual. How

well these educated pastors built is shown by the fact that our churches, educational systems, and medical schools are the results of a natural development from seeds planted in Colonial days by the leaders of institutions of higher learning.

The training of physicians is the phase of higher education that is now the most widely advertised among the people, for every person must come into intimate contact with a doctor at some time during his life. The needs of medical schools are now emphasized as never before, and universities are conducting campaigns for millions of dollars of endowments, with every prospect of success.

A medical school was a source of financial profit in the days when it consisted of merely a lecture hall and a dissecting room, and an annual tuition of one hundred dollars yielded a large balance to be distributed among the professors who owned the school. But with the develop-

THE DISCOVERY OF OXYGEN

Physicians will recall that when they were medical students, they were taught in an impersonal way that oxygen was discovered by Priestley in the year 1774. It is with a thrill that one reads in the January number of the *Journal of the Iowa State Medical Society* that his great-grandson, Dr James Taggart Priestley died in Des Moines on December 11, 1925, after a long life of usefulness and honor spent in the practice of medicine and in high administrative offices in his State Society and the American Medical Association. The *Journal* also states that this Dr James T Priestley had a son who died in 1904 after practicing medicine ten years, that two grandsons are now medical students in the University of Pennsylvania, and that several members of the Priestley family in previous generations had been physicians.

As one reads the biographies of the members of the Priestley family, one is struck with their hereditary characteristics. Of Dr James T Priestley, the *Iowa State Journal* says

"If the special characteristics of Priestley are recalled, all will agree that the striking feature is his versatility. The rare faculty of adapting himself to all conditions in every circle, lay or professional, cultured or illiterate, is his. He easily dominates by the charm of his personality. Travel has been his hobby, and there are probably very few regions of the globe open to the traveller with which he is not familiar. His knowledge of human nature and broad culture have been strong elements in his development as consultant and physician."

These characteristics seem also to have belonged to Joseph Priestley, the discoverer of oxygen, who was a minister of the Gospel in an unconformist Church of England, and came to America in 1794 at the age of 61 on account of the difficulties arising from the French Revolution, but his decision to emigrate was probably influenced by the fact that his three sons were already settled in Pennsylvania. He died at the age of 71 in Northumberland, Pennsylvania, in 1804 while serving as pastor of a Unitarian church in that town.

Joseph Priestley was a pastor during all his active life, but he was deeply interested in all phases of natural history, on which he wrote much as well as on theology. He began the chemical study of gases in the year 1767 when he lived next door to a brewery where he could obtain a ready supply of carbonic acid gas. He seems to have held no scientific appointments, and to have received no assistance from colleges or endowments, but he devised his own apparatus and paid the bills out of his own meager resources. He continued his studies in Pennsylvania, and was the close friend of Benjamin Franklin.

Priestley's name is linked with that of Antoine Laurent Lavoisier, who was an amateur in chemistry and made his investigations while discharging his duties as an official in scientific departments of the French Government. He fell a victim to the Reign of Terror in 1794. The work of Priestley and Lavoisier must be considered together in order to understand what they did.

The ancient idea was that all matter was composed of four elements—earth, water, air and fire, representing solids, liquids, gases and heat. Solids were analyzed one after another in a crude way, and a considerable practical knowledge of metals was developed. But water, air, and fire defied analysis until Priestley and Lavoisier found the key to their secrets.

About one hundred years before their time, the crude conception of fire as an element had been replaced by the theory of 'phlogiston', which is derived from the Greek *phlox*, flame. About all that the phlogistic theory amounted to was the substitution of the word phlogiston for fire in the list of elements, and the assumption that phlogiston was a constituent of all matter, which became perceptible when burning occurred. Lavoisier proved the inconsistencies of the phlogiston theory by the use of accurate balances by which he showed the unchangeableness of the weights of the constituents that enter into chemical reactions. He was also an investigator of the phenomena of heat in association with the astronomer La Place, and had he not been sacrificed by the ignorant revolutionists, he would probably have discovered the constancy of the heat involved in chemical reaction.

The outstanding work of Priestley was the analyses of air and other gases. Carbon dioxide, the product of ordinary combustion, was known as fixed air, and was considered to be air deprived of phlogiston, and therefore incapable of supporting combustion. Hydrogen, the gas given off from metals which were attacked by acids, was called inflammable air.

Priestley performed a great number of experiments and investigations with what he himself said was largely an aimless purpose, for he had no preconceived theory which he wished to prove. He simply made experiments and recorded their methods and their results. The manufacture of bone black by the distillation of bones and horns yielded an ammoniacal liquid called spirits of hartshorn. On heating the liquid, Priestley got what he called alkaline air—ammonia—from which he synthesized sal ammoniac—ammonium chloride—by its treatment with hydrochloric acid. He heated red oxide of mercury by means of a burning glass, and got oxygen, which he called phlogisticated air for it supported both combustion and respiration.

THE INTERSTATE POST GRADUATE CLINIC TOUR ABROAD

The second foreign tour of American physicians is announced to start on April 28th from New York City on the "Araguaya" of the Royal Mail Steam Packet Line. The tour is under the auspices of the Inter-State Post Graduate Assembly of North America, which is a development of the Tri-State Medical Society.

This organization has its headquarters in Freeport, Illinois. It has conducted a series of pilgrimages to medical centers in the United States, and last year it conducted a tour to the medical centers of the British Isles and Paris. The foreign tour was a success and was taken by five hundred doctors and two hundred and fifty members of their families. Medical lectures were held on the boat every day of the ocean trip, and the members were cordially received by the hospital authorities and the officials of the cities that were visited. Science, sociability, and sight-seeing were happily combined during the whole six weeks of the trip. The spirit of the members is indicated by Dr. Tasker Howard in the *Long Island Medical Journal*, January, 1926, who said of the tourists: "Sixty-five per cent were general practitioners, men of wide experience, shrewd judgment, and ambition. The other thirty-five per cent were surgeons or specialists of one kind or another. The average level of medical accomplishment was very high, in spite of the scarcity of nationally known figures (The eminent advisory board contributed prestige by the luster of their names and mostly stayed at home). The atmosphere of the party exempli-

fied the American spirit at its best, a medical democracy, each member ready to give and take, none presuming superiority. There was evident a serious purpose, but laughter never was very far below the surface."

This year's trip is planned along the lines of that of last year. The party will land at Cherbourg, and will visit Paris, Rome, Florence, Pisa, Bologna, Padua, Milan, Berne, Zurich, Munich, Vienna, Prague, Berlin, Amsterdam, The Hague, Utrecht, Leyton, and Brussels. Dr. Carl Beck, of Chicago, General Secretary of the Organization, is now abroad completing the arrangements for the trip.

General information regarding the trip is contained in a twenty-four page folder which has been extensively distributed. It contains the portraits of eighteen prominent physicians and surgeons who are either officers of the organization or sponsors for the trip, and an eight-page list of notable medical men who are sponsors for the tour—132 Americans, and 217 foreign physicians. The cost of the tour is about \$1,500 for first-class accommodations, but arrangements may be made for a part of the trip.

A second section of the tour is announced to leave New York on June 19, and returning to leave Europe on August 19 from Antwerp.

The popularity and success of last year's tour will doubtless influence the medical men of America to over-subscribe to the quota which can be accommodated on this year's tour.

LOOKING BACKWARD

The *New York State Journal of Medicine* for February, 1901, contains an eulogy of Dr. Leroy J. Brooks, who died on December 11, 1900, at his home in Norwich, where he had practiced medicine for twenty-six years.

Dr. Brooks was noted for his public spirit and his conscientious performance of every duty. He was faithful to his patients and to his brother practitioners and their societies. His fine character is revealed in a short poem which he wrote only two weeks before his death, of which two verses read:

"Help me to know just what is best,
What hidden purpose thou didst have for me,
Let me, O Lord, e'en in this enforced rest,
Find something yet that I can do for Thee,
"Help me by faith to bravely walk
The path unlighted which I cannot see
Hold fast my hand and to me talk
Till I unquestioning put all trust in Thee."

Dr. Brooks was the father of the present Deputy State Commissioner of Health.

ment of bacteriology, biological chemistry, electro-therapy, and other sciences, expensive laboratories had to be maintained, and the cost of the one item of guinea pigs of a modern laboratory exceeds that of the dissecting material of pre-bacteriological days. The medical schools today report an annual cost of maintenance approaching twelve hundred dollars per student, which is offset by a tuition fee of about three hundred dollars. Every medical student in the land is the recipient of a gift whose money cost exceeds that of the donation to a theological student. The medical profession probably heads the list of the learned professions in the amount of public money, or endowment which is allocated to each student as an overhead charge upon the institution.

The medical schools of the Northern States are the recipients of millions of dollars of endowments from the wealth that surrounds them, but the schools in the Southern States are also receiving great endowments. Duke's University is planning a medical school in North Carolina that shall equal that provided by Mr. Eastman of Rochester. The Vanderbilt University Medical School of

Tennessee has secured an endowment which is worthy of the excellent medical work done by the school in the past. And now Emory University in Atlanta is appealing for an endowment of ten million dollars, nearly one-half of which will be for the benefit of the Medical Department.

The Medical School of Emory University is adopting the unusual plan of making an appeal through the State Medical Association of Georgia. A letter of appeal from Dr. Allen H. Bunce, Secretary of the State Association and Editor of its Journal, states:

"For many years the school has been handicapped both in research and in teaching work because of inadequate endowment. The enrollment in each class has been limited to sixty men at a time when more physicians of Georgia alone are dying each year than the two medical colleges of the State are graduating. The school is looking to its alumni and to other friends of medical education to give funds so urgently needed for expansion."

It is gratifying to note the cordial relations of the Medical Department of Emory University with the official medical society of its State.

PHYSICIANS IN RURAL COMMUNITIES

A survey of rural communities made soon after the war indicated that in many places as the older physicians died or retired, no other doctors took their places. The statistics were interpreted to indicate that in a decade or two the people of rural communities would be unable to obtain medical service.

A conference on the subject of rural medical service was held in the spring of 1923 under the joint auspices of the State Department of Health of the State Medical Society, and the consensus of opinion was that the advent of automobiles and good roads enabled a doctor to make his visits over a radius of ten miles as readily as over one of three miles a decade ago. It was further shown that the critical period of medical need was during and immediately after a heavy snow storm when the roads would be impassable and visits over a mile away would be almost impossible under any conditions of supply of doctors.

While there was no general need for additional doctors in rural communities, a few isolated places needed doctors. A few places in the Adirondack Mountains were seeking doctors and the towns were offering considerable salaries as inducements to doctors who would settle there. But difficulty in securing doctors arose from the fact that physicians from the city flocked to the mountains during the summer season and took

the cream of medical practice, and left the local doctor to do the hard unremunerative work during the season of blizzards. It is not the blizzards and the long drives that keep doctors out of the rural communities, but it is the competition of city doctors who seek to meet the expenses of their vacations by taking cases that properly belong to their rural confreres.

The rural people, too, are somewhat to blame when they employ the city man because he is nearby, or appears to be more available than the local doctor.

Now and then a call for a doctor comes from a rural community in which there is an excellent organization of physicians. Such calls for assistance have come from Chautauqua and Steuben Counties.

The State Department of Health has adapted the policy that when it receives a request for a doctor, they shall refer the request to the State Medical Society. During the two years that the policy has been in force the bona fide calls for assistance have been few. However, the Medical Society of the State of New York is ready to assist any community to secure a doctor. It prefers that the call for assistance should come through a county medical society or a group of physicians who are familiar with local conditions.

regular rhythm was established in 70 per cent, while in the degenerative group only 40 per cent became regular. The average amount of drug necessary to bring about sinus rhythm in the mitral group was 1.142 Gm, while in the degenerative group it was 1.450 Gm. The average duration of regular rhythm in the mitral group was 90 days, while in the degenerative group it was 20 days. The average duration of the auricular fibrillation in those who became regular after quinidine had been five months, while in those who did not respond the average duration had been 19 months.

To those patients who could be kept under observation after the establishment of regular rhythm, quinidine was usually given in daily doses of from 0.2 to 0.6 Gm for a few weeks in order to prevent an early relapse.

In *transient* auricular fibrillation, quinidine was found to be indicated only when the arrhythmia persisted after the disappearance of the transient causative factor. In cases associated with hyperthyroidism, quinidine apparently should not be used until six weeks after thyroidectomy. In *paroxysmal* auricular fibrillation not due to hyperthyroidism, in which paroxysms were frequent, quinidine administered prophylactically, in doses of from 0.2 to 0.4 or 0.8 Gm daily, was found to be of the greatest value in lengthening the interval between the attacks and in shortening the paroxysms that did occur. In the treatment of individual paroxysms, quinidine was called for only in rare instances when the paroxysm tended to be prolonged. Quinidine in daily doses was not necessary unless the paroxysms occurred more often than once in two weeks. In the mitral disease group quinidine should be used only in the absence of cardiac hypertrophy and dilatation, when the irregularity has existed for but a short time and there is no congestive cardiac failure. In the degenerative group, the authors are inclined to believe that the use of quinidine is not justified. The chief value of the drug was found in the treatment of frequent paroxysmal auricular fibrillation when not associated with hyperthyroidism. It has many dangers and an extremely limited field of usefulness in the established cases, and real benefit of considerable duration is derived in only a small proportion of these. One death occurred in association with quinidine therapy in the series of cases of the established type.

Angina Pectoris Without Anatomical Basis
—A case of this type was reported recently by Gruber and Lanz. The patient had died in the midst of an "epileptic" seizure and the absence of all lesions at autopsy gave rise to the opinion that a fatal spasm of the coronary arteries had accompanied a similar process in the encephalon which produced the fit. The myocardium appeared to be in a condition of ischemia although

the vessels were quite intact. This same case is commented upon in greater detail by Kohn in the *Muenchener medizinische Wochenschrift* of December 11, 1925. There was no remote history worth mentioning, the evidence in favor of an epileptic seizure was defective, although the patient appeared to have had several similar seizures shortly before admission to the clinic, and there was a doubtful history of an anginous attack also shortly before admission. The microscope showed changes in the heart which could hardly have occurred more than four days before death—an ischemic necrosis—while the first epileptic seizure was said to have occurred some nine weeks before admission. The vascular spasm in the coronary arteries, to have produced ischemic necrosis, must have been both prolonged and intense. The author dismisses the idea that the patient was an epileptic, for the seizures were atypical at best. The patient's pulse presented nothing abnormal during his short sojourn in the hospital, else one might think of an epileptiform attack resulting from heart-block. The author is inclined to believe that the case was nothing more or less than a sustained spasm of the coronaries lasting some six minutes and producing death by total arrest of the heart's action. The supposed seizure would then be only a terminal convulsion, having nothing in common with epilepsy. The importance of the case lies chiefly in its testimony that not only may angina pectoris be due solely to spasm of the coronaries but that such a functional spasm may in itself be fatal.

Operative Treatment of Angina Pectoris — Goldscheider contributes an article well calculated to give the exact status of this subject. He first isolates three distinct types of intervention: (1) Sympathectomy in the original Jonnesco sense in which the cervical and first thoracic ganglia are extirpated. (2) Extirpation of the superior cervical ganglion only, on the supposition that the reflex arc is thereby interrupted by division of the cardiac vasoconstrictor fibres (Coffey and Brown operation). (3) Division of the depressor vagi on one or both sides (Eppinger and Hofer operation). The theoretical justification of surgical intervention is that thereby the pain-registering fibres are divided. We know little enough about pain in the heart and aorta, although there are sensory fibres in the adventitia of the latter. The wisdom of abolishing pain is sometimes dubious for we may be changing an active to a latent and insidious process. In dividing these fibres we may also interfere with the blood supply of the myocardium. The author gives five different explanations of the painful crises and of their relationship with organic disease of the heart. He does not endorse the scepticism of Wenckebach in regard to coronary spasm as the cause of the pain, and enumerates many reasons for his

MEDICAL PROGRESS

An Initial Syndrome of Gangrenous Appendicitis—R M Rowe (*Lancet*, Dec 19, 1925, civ, 5338) calls attention to the value of what he terms the "epigastric syndrome" in enabling one to recognize, at the beginning of the illness, a form of appendicitis which calls for early operation to anticipate the certain onset of gangrene and perforation. This group of signs is to be met with quite at the beginning of the gangrenous form of appendicitis. It is well marked during the first six hours and well in advance of the classical signs in the right iliac region. The patient must be seen within the first six hours or so after the onset of the symptoms, because after that the syndrome in question tends to disappear, and when the surgeon and physician meet in consultation may have vanished with hardly a trace. It will not be met with in hospital practice, for patients seen there do not come to the surgeon early enough. The patient—a child or young adult most commonly—complains of violent pain referred to the epigastrium. There is usually vomiting, but the knees are not drawn up. An abdominal examination shows marked tenderness, localized in the left upper epigastric region, with cutaneous hyperesthesia within the same limits. The upper segment of the left rectus muscle is in a state of contraction and feels rigid on palpation. The right iliac region, on the contrary, betrays neither swelling, rigidity, tenderness, nor hyperesthesia, at this stage of the process. The temperature is often slightly raised—99° to 100° F—and may become normal again as the syndrome passes. The pulse is a more reliable guide—90 to 120—and either does not decline with the fall of temperature or becomes progressively faster and shows increasing tension. The duration of the syndrome varies, it is most apparent during the first six hours of the attack, but it may still be recognizable in part so long as 18 or 19 hours after the beginning of the epigastric pain. The last element to disappear is the tonic of the left rectus. The practical point is that the syndrome is transient, and this being so, it is important to recognize it at the beginning of an attack, since it is a definite warning of the gravity of the process and an indication for immediate operation.

In a former article in *La Presse Medicale* of May 5, 1923, the author says that laparotomy at this stage would show the great omentum approaching the appendix, the interval varying with the progress of the disease, eventually, it will reach the appendix and be closely approximated to it. The appendix itself will be the seat of a patch of gangrene through which perforation

may occur. The author is unable to account for the syndrome, but evidently it stands in some close association with the irritated condition of the great omentum, or if not this, the mechanism must be a reflex involving the solar plexus and vagus.

The Dietetic Treatment of Ulcer of the Stomach—After discussing the dietetics of ulcer of the stomach as practised by the Leube and Lenhartz methods, Alexander J. Jarotzky (*Therapeutic Gazette*, December 15, 1925, 3rd Ser., vi, 12) outlines a procedure which has given highly satisfactory results in his hands. A patient suffering from ulcer of the stomach, even immediately following acute hemorrhage, is given one raw white of egg (without salt) on the morning of the day following admission, and 20 grams of good, fresh-cream butter (without salt) in the evening. On each of the following days the number of the whites of egg is augmented by one, and the amount of butter by 20 grams, until the number of whites of egg amounts to eight and the quantity of butter to 160 grams. The diet can be continued for ten to twelve days. The patient is allowed no other food, drink or medicaments. This diet is recommended as giving the most perfect rest to the stomach in ulcer of the stomach and duodenum, in poisoning by corrosive acids and alkalis, when one may fear peritonitis from perforation of the ulcer, in the treatment of illness accompanied by excessive secretory function of the stomach (hyperchlorhydria), gastrosuccorhea and the like, following operations on the stomach and in any condition in which complete rest for the stomach is indicated.

Quinidine in the Treatment of Auricular Fibrillation—F. Janney Smith and Norman E. Clarke report their experience with the administration of quinidine in cases of certain types—paroxysmal, transient and established—of auricular fibrillation (*Archives of Internal Medicine*, December 15, 1925, xxxvi, 6). In the group of cases (20) of established auricular fibrillation, normal rhythm was produced in 61 per cent by a one-day plan of quinidine administration. All the patients had previously received sufficient digitalis to slow the ventricular rate below 90 per minute, the drug being then discontinued. A test dose of 0.2 to 0.4 Gm. was given the first day, and during the day following 2.4 Gm. or less was administered in increments of 0.4 Gm. The cases were equally divided between the arteriosclerotic, the senile or degenerative type, and those in which mitral disease was the main contributing factor. In the mitral disease group,

regular rhythm was established in 70 per cent, while in the degenerative group only 40 per cent became regular. The average amount of drug necessary to bring about sinus rhythm in the mitral group was 1.142 Gm., while in the degenerative group it was 1.450 Gm. The average duration of regular rhythm in the mitral group was 90 days, while in the degenerative group it was 20 days. The average duration of the auricular fibrillation in those who became regular after quinidine had been five months, while in those who did not respond the average duration had been 19 months.

To those patients who could be kept under observation after the establishment of regular rhythm, quinidine was usually given in daily doses of from 0.2 to 0.6 Gm. for a few weeks in order to prevent an early relapse.

In *transient* auricular fibrillation, quinidine was found to be indicated only when the arrhythmia persisted after the disappearance of the transient causative factor. In cases associated with hyperthyroidism, quinidine apparently should not be used until six weeks after thyroidectomy. In *paroxysmal* auricular fibrillation not due to hyperthyroidism, in which paroxysms were frequent, quinidine administered prophylactically, in doses of from 0.2 to 0.4 or 0.8 Gm. daily, was found to be of the greatest value in lengthening the interval between the attacks and in shortening the paroxysms that did occur. In the treatment of individual paroxysms, quinidine was called for only in rare instances when the paroxysm tended to be prolonged. Quinidine in daily doses was not necessary unless the paroxysms occurred more often than once in two weeks. In the mitral disease group quinidine should be used only in the absence of cardiac hypertrophy and dilatation, when the irregularity has existed for but a short time and there is no congestive cardiac failure. In the degenerative group, the authors are inclined to believe that the use of quinidine is not justified. The chief value of the drug was found in the treatment of frequent paroxysmal auricular fibrillation when not associated with hyperthyroidism. It has many dangers and an extremely limited field of usefulness in the established cases, and real benefit of considerable duration is derived in only a small proportion of these. One death occurred in association with quinidine therapy in the series of cases of the established type.

Angina Pectoris Without Anatomical Basis

—A case of this type was reported recently by Gruber and Lanz. The patient had died in the midst of an "epileptic" seizure and the absence of all lesions at autopsy gave rise to the opinion that a fatal spasm of the coronary arteries had accompanied a similar process in the encephalon which produced the fit. The myocardium appeared to be in a condition of ischemia although

the vessels were quite intact. This same case is commented upon in greater detail by Kohn in the *Muenchener medizinische Wochenschrift* of December 11, 1925. There was no remote history worth mentioning, the evidence in favor of an epileptic seizure was defective, although the patient appeared to have had several similar seizures shortly before admission to the clinic, and there was a doubtful history of an anginous attack also shortly before admission. The microscope showed changes in the heart which could hardly have occurred more than four days before death—an ischemic necrosis—while the first epileptic seizure was said to have occurred some nine weeks before admission. The vascular spasm in the coronary arteries, to have produced ischemic necrosis, must have been both prolonged and intense. The author dismisses the idea that the patient was an epileptic, for the seizures were atypical at best. The patient's pulse presented nothing abnormal during his short sojourn in the hospital, else one might think of an epileptiform attack resulting from heart-block. The author is inclined to believe that the case was nothing more or less than a sustained spasm of the coronaries lasting some six minutes and producing death by total arrest of the heart's action. The supposed seizure would then be only a terminal convulsion, having nothing in common with epilepsy. The importance of the case lies chiefly in its testimony that not only may angina pectoris be due solely to spasm of the coronaries but that such a functional spasm may in itself be fatal.

Operative Treatment of Angina Pectoris —

Goldscheider contributes an article well calculated to give the exact status of this subject. He first isolates three distinct types of intervention: (1) Sympathectomy in the original Jonnesco sense in which the cervical and first thoracic ganglia are extirpated. (2) Extirpation of the superior cervical ganglion only, on the supposition that the reflex arc is thereby interrupted by division of the cardiac vasoconstrictor fibres (Coffey and Brown operation). (3) Division of the depressor vagi on one or both sides (Eppinger and Höfer operation). The theoretical justification of surgical intervention is that thereby the pain-registering fibres are divided. We know little enough about pain in the heart and aorta, although there are sensory fibres in the adventitia of the latter. The wisdom of abolishing pain is sometimes dubious for we may be changing an active to a latent and insidious process. In dividing these fibres we may also interfere with the blood supply of the myocardium. The author gives five different explanations of the painful crises and of their relationship with organic disease of the heart. He does not endorse the scepticism of Wenckebach in regard to coronary spasm as the cause of the pain, and enumerates many reasons for his

belief that this spasm is the essence of the disease. Allbutt's justification that the pain originates from spasm of the aorta he has never seen in the original and hence withholds his criticism. However whether coronaries or aorta be at fault does not immediately concern the policy of surgical intervention. The problem of correct diagnosis of angina is of much greater significance, and he mentions numerous affections which have been confounded with it. Finally comes the diagnosis of when and how to intervene, which is being abundantly discussed by the surgeons. The paper closes with a report of two fatal unpublished operative cases (Sorenson, Brüning). —*Klinische Wochenschrift*, December 17

Cardiorrhaphy—J. H. Long (*Boston Medical and Surgical Journal*, December 24, 1925, cxiii, 26) describes two cases of stab wounds of the heart in which suture of the wound was followed by complete recovery. In the first case, on exposure of the heart, the tip of the auricular appendix and upper margin of the pericardial opening were withdrawn from a hole about one-half inch long in the anterolateral wall of the left auricle. A continuous chromic suture was passed through the pleuro-pericardial membrane, myocardium and endocardium, and the chest wound was hurriedly closed. There were no ill-effects from this method of suture, and it added much to the firmness of closure. The sutures were introduced during diastole, this being regarded as the most convenient time during the cardiac cycle. In the second case, there was an incision one inch long in the pericardium and a wound in the ventricle which admitted the tip of a finger. This was closed with one chromic suture. The pericardial and pleural sacs should be closed without drainage. Free communication between these cavities is compatible with good health in animals, and it has been suggested that if such communication were left in cases operated upon, the mortality might be reduced. This was done in the author's second case. Cardiorrhaphy has raised the percentage of recovery in cases of heart wounds from 10 to 40.

Cholin in Paroxysmal Tachycardia—Stepp and Schliephake report the case of a young man with frequent attacks of paroxysmal tachycardia due to auricular flutter, with a maximum pulse rate of 240 per minute. Cholin injection brought it down in five minutes to 80, the patient at the same time complaining of a sense of constriction in the chest and salivation. Since suggestion has been known to interrupt these attacks the authors used other drugs by injection but always with a negative result. During a period of eight months 60 cholin injections were given. No practical conclusions can be drawn from one case and the authors make no suggestions about the use of cholin in the clinic, save that it should be a valu-

able synergist to strophanthin. It is suggested that the remedy may be given intravenously in the dose of 0.5 c.c. of a 5 per cent solution of cholin chlorate.—*Muenchener medizinische Wochenschrift*, November 20, 1925

Diagnosis of Syphilis From the Blood Picture.—Anton of Hamburg states that for several years he has been at work on this problem, but until recently with chiefly negative results. The dark field illumination, vital staining and other resources led only to failure. However, he had the firm conviction that the blood contamination with the spirochete at the first explosion of the disease should leave its mark in some way and thereby give us a more rational and trustworthy test than the Wassermann reaction, which is neither truly specific nor always dependable, since a negative seroreaction may not exclude the disease. Recently, the discovery of a new stain gave the author his first success in that it causes a characteristic change in the nuclei of the leucocytes which appears to be of the nature of a chromatolysis. He withholds for the time being the exact technique of staining, but in essence he fixes thin blood smears with methyl alcohol and stains with a formula of methylene blue. Thus far, he has examined the blood of about 200 syphilitics with every clinical type of the disease, save the first of the primary sore period, and has not found the blood picture absent even in metasypilis and congenital lues, nor has he ever found it in other than syphilitic subjects. Thus far, he is unable to advance any views as to the mechanism of this alteration in the leucocytes nor is it possible to tell from it anything concerning the stage or degree of severity of the disease. It is well known that in the different stages and intensities there are various alterations in the blood picture, but thus far nothing specific of syphilis had been shown to be present until the author made his staining discovery.—*Archiv f. Dermatol u. Syphilis*, Nov 20, 1926 (cxlix, No 3)

The Teeth in Congenital Syphilis—The original teaching of Hutchinson regarding the dental anomalies in congenital syphilis has been so modified by numerous modern reports as to leave it hardly recognizable. The general trend of the present-day teaching is that there are numerous dystrophies of the teeth, by no means specific in character, which are in the main due to hypoplasia of the enamel, coming under the head of erosions. But Pflüger, of the Dental Department of the Hamburg-Eppendorf Hospital, after years of original investigation, goes back to the Hutchinsonian views which he endorses in every respect. In other words, the notching of the upper central incisors he regards as an eminently specific lesion found only in congenital syphilis, the deformity being due to some vice of development

limited to the middle third of the maxillary denture. One naturally asks how the Hutchinson doctrine became sidetracked, and this question is not difficult to answer. After the British author had published his classic, some of his enthusiastic French colleagues, among them Parrott and Fournier, took up the subject where Hutchinson had stopped and began to add to the clinical manifestations until much confusion was produced. During the present century, a whole body of statement has been supplied by stomatologists and syphilographers, in which the prevailing note has been that alleged dental anomalies attributed to syphilis in reality occur in a variety of conditions, while congenital syphilitics may not present dental anomalies of any kind. The present state of our knowledge is as follows. In congenital syphilis the upper middle incisors present characteristic pictures, such as the notched edge and the "chisel" and "screw-driver" shapes. The changes, however, are by no means limited to these teeth. The many lesions added by other authors are not specific and are due to hypoplasia of the enamel, so that they occur under various circumstances and may coexist with "Hutchinson's teeth," although merely by coincidence. Symmetry is not necessarily present.—*Archiv f. Dermatologie u. Syphilis*, Nov 20, 1925 (cxlix, 3).

Studies of Certain Hitherto Undescribed Antirachitic Substances.—In former communications Andor de Bosanyi (*Bulletin of the Johns Hopkins Hospital*, January, 1926, xxxviii, 1) showed that watery extracts of defatted bone-marrow caused healing when they were administered to rickety animals. Since the bone-marrow from which these substances were made was defatted, and the extracts themselves were subjected to dialysis, the organic matter must have consisted in a large part of protein. Among these proteins hemoglobin, histons, nucleoproteins, fibrogen, and globulins are the most notable, there are also some xanthin bases, cholesterolin, inositol, lactic and uric acids, and certain pressor substances. Experiments were carried out to determine to which of these substances the specific antirachitic effects were due. Rats were made rachitic by standard rickets-producing diets and then treated with these substances, given separately. It was found that healing might be induced by a histon—the globin of hemoglobin, a diamido acid, cystin, an aromatic compound, adrenalin, and an alkaloid, pilocarpine.

Therapeutic Softening of Scar Tissue.—In an article in the *Muenchener medizinische Wochenschrift*, of December 11, 1925, Professor Stoeltzner of Koenigsberg says that in 1911 he saw a remarkable result from fibrolysin in which a post-pneumonic retraction, with scoliosis, underwent complete resolution. Since that time,

however, due no doubt to employment of the remedy in unsuitable cases, surgeons have become more or less sceptical about the virtues of thiosinamin, but the author has never lost interest in the idea and has sought particularly to find an improvement on the original formula of fibrolysin, which, as is known, is an 87 per cent solution of thiosinamin. On account of its increased solubility in aqueous solutions of urea (25 per cent) he was able to increase the strength to more than 10 per cent. At first the author contented himself with experiments *in vitro* in dissolving in the new solution connective tissue and fibrils of scar tissue, also collagen and gelatin. Of importance are experiments in lowering the solidification threshold of gelatin solutions and in this connection it was possible to add various salts to the author's solution as synergists. Many salts known to lower this point were tested and the composition of the solvent was also varied, using mixtures of alcohol and water. As is known fibrolysin contains sodium salicylate. The author found that the best solvents were urea (present of course in thiosinamin as well), cholin, potassium, and sulphocyanides. His best formula seems to have been a saturated solution (50 per cent) of urea as a solvent and in addition to the 10.1 per cent of thiosinamin, 1.5 per cent of potassium sulphocyanide. Dura mater was used as a test-substance.

The practical results of this treatment of scars is given in a complementary article by Stoye, Professor Stoeltzner's assistant in the chair of Pediatrics in Koenigsberg. The material for these therapeutic tests was found chiefly in the surgical clinic of Professor Voelcker of Halle. A case given in detail was one of extensive scar formation following burns of the face and breast in a child of six years, who was seen by the author at the age of fifteen. It had been necessary to divide the scar tissue to enable the child to move her head and arm, but there was still very great deformity and limitation of motion. In beginning the treatment various solutions were used for mutual control, injected directly beneath the scar. The solution mentioned in Stoeltzner's article and another containing iodide in place of sulphocyanide of potassium gave the best results. Treatment was begun March 21, 1925, and continued to March 31, injections were made daily in several places and active and passive motion, also practised daily, showed the rapidity with which the scar tissue yielded. The patient has been under observation since and the improvement is seen to be permanent. The author has treated many other cases of scarring and concludes that, while brilliant results are seen in suitable cases, he cannot recommend the treatment for adherent scars because of the tendency to necrosis. One should also wait until the cicatrizing process has reached its completion.

LEGAL

CLAIMED DIAGNOSIS OF GALL STONES INSTEAD OF APPENDICITIS

In this action the defendant physician was sued to recover for the damages claimed to have been suffered by the plaintiff as administrator of his decedent. It was charged that the defendant negligently and carelessly diagnosed the ailment of the decedent as gall stones, when in fact she was suffering from appendicitis, and that by reason of his improper diagnosis there was a delay in the performance of the appendectomy resulting in the setting in of peritonitis and the subsequent death therefrom of the decedent.

The defendant physician had attended and treated the decedent at various times for different ailments. On May 25th, at about 2 P M., he was called to the patient's home, at which time he found her in bed and complaining of pains in the stomach, and she stated that she felt like vomiting. Upon an examination of the abdomen no objective symptoms of appendicitis were found except a slight tenderness and slight rigidity of the muscles of the abdomen. Her temperature and pulse were normal at this time. The physician ordered the application of a hot water bottle and the administration of a hot water injection. He returned in about two hours, at which time she was still complaining of the abdominal pain. The patient inquired of the physician whether he thought she was suffering from gall stones. The abdominal examination made at this time disclosed the same condition as on the previous examination. He advised that the patient be removed to the hospital, but she refused to go at that time, stating that she would have to await the return of her husband in the evening. The physician had arranged to return to the patient's home at about 8 o'clock that evening. Shortly before this hour he received a telephone call from the patient's husband stating that the patient was better and that the doctor need not call unless he was sent for.

At about 2 A M. of the following morning the husband again telephoned to the physician's office stating that the patient again had the pains. The physician at that time advised the application of an ice bag. At about 5 A M. of the same morning the physician received another telephone call and immediately went to the home of the patient whom he found in bed and complaining of intense pain in the abdomen. He directed that she immediately be sent to the hospital and in ambulance was called. She was removed to the hospital at about 6 A M. At about 8 A M. a urine and blood examination were made by the pathologist at the hospital, the blood examination disclosing the presence of a large quantity of white

cells. The patient was immediately prepared for operation, and an appendectomy was performed by the defendant under a general anaesthesia. Upon opening the abdomen the appendix was found to be gangrenous, and was removed and a rubber drainage tube inserted. The abdominal wound was then sewed and the patient returned to bed and placed in shock position by raising the head of the bed. The defendant physician remained with the patient until she came out of the ether about two hours later. He placed her in charge of two graduate nurses, and called upon her three times thereafter during that day. After the operation the patient's temperature rose to about 103 degrees. The doctor called upon her three or four times the following day and there was a slight improvement in her condition with a small decrease in temperature. Her condition continued to improve until May 29th, when the temperature suddenly rose to about 104 degrees, and the patient became cold and restless. The defendant physician had hot water bottles applied to her feet, and ordered that she be well covered up. From this time on her condition did not improve, and her pulse became weak. Stimulation was administered to her, the defendant staying with the patient and constantly watching her. The temperature decreased one degree and then suddenly rose again to 105.8 degrees at the time of the death of the patient at about 10 A M. on May 30th. A death certificate was issued by the house physician of the hospital, giving the cause of death as general peritonitis with the contributory cause of gangrenous appendicitis.

At the time of the trial the plaintiff introduced various lay members of the family to testify that when the defendant was first called he diagnosed the condition of the decedent as gall stones, and that in answer to an inquiry as to whether the patient was suffering from appendicitis he had answered in the negative, and that at the second visit made by the defendant he still insisted that the ailment of the decedent was gall stones and not appendicitis, and that there was no necessity for the patient being operated upon or removed to the hospital, and it was not until the visit at 5 A M. on the morning of May 26th that he made his diagnosis of appendicitis. The lay witnesses likewise testified to the symptoms and complaints of the patient. Upon this testimony the plaintiff introduced a physician as a witness, who testified as an expert, that from all of the symptoms the patient was suffering from appendicitis and not from gall stones, and that the defendant should have diagnosed the condition as such, likewise

that the application of heat to the abdomen and his failure to visit the patient as testified by the plaintiff's witnesses, was a competent producing cause to extend or increase the peritonitis and result in the death of the patient. It was likewise the opinion of this physician that the gangrenous condition of the appendix had set in between 10 A M and 2 P M of May 25th, which was the time when the defendant was first called to attend the decedent. The defendant in his own behalf testified as to various calls upon the patient and the examinations made at those times, and

his tentative diagnosis of appendicitis and a subsequent diagnosis of appendicitis, which was borne out by the operation. He likewise introduced the testimony of the physicians who had assisted him in the performance of the operation, and that of physicians who testified as experts that the procedure of the defendant was in accordance with the proper and approved practice.

At the close of all the evidence the case was submitted to the jury which, after several hours of deliberation, returned a verdict in favor of the defendant.

PREGNANCY—PYELITIS SUBSEQUENT TO DELIVERY AND RESULTANT HYSTERECTOMY

In an action instituted against two physicians in August, 1922, it was charged that they were engaged in September, 1919, to deliver the plaintiff of a child, that they failed to give usual and ordinary careful treatment, with the result that the plaintiff's body and blood became infected, causing the removal of the plaintiff's generative organs.

One of the defendants was engaged for the confinement a few months ahead of the expected period and about the middle of September, 1919, he delivered the plaintiff. The delivery was regular, with a normal labor in every respect, no lacerations, and a normal vertex birth. Her condition remained normal until the afternoon of the third day after the birth, when the defendant was called to the hospital and informed that the patient had had a chill and was running a temperature of 102 and 103 degrees. The chills and temperature persisted and two days thereafter when he made the vaginal examination he found nothing wrong, no pain, no masses or evidence of inflammation in the pelvic organs. On the 9th day after the birth the defendant called another physician in consultation, who likewise made a complete physical examination and found nothing wrong in the pelvis of the patient. He found no evidence of any inflammation, the fallopian tubes were normal and the uterus had continued normally to involute. The plaintiff continued running a temperature with no apparent cause therefor.

The patient was catheterized and the urine analysis disclosed that she was suffering from pyelitis and she was thereupon given the proper treatment for this condition. The patient was removed to her home, where her child was also ill with pyelitis. The defendant there continued to treat both the mother and the child, taking frequent urine specimens which, upon analysis,

showed the presence of pus. The mother developed a pain in the abdomen and the second defendant was called in consultation. He made a physical, bi-manual and vaginal examination and was of the opinion that the plaintiff was beginning to develop localized trouble in one side of her pelvis. He recommended the continuation of the present treatment and that it would be safer to let the condition localize before operative methods were resorted to. A special vaccine was prepared and administered to the plaintiff. She was also treated with ice bags and hot water douches. As her condition did not improve in about three days, she was removed to the hospital with which the second defendant was connected, where the treatment was continued for about a week, when the second defendant was arbitrarily dismissed from further treatment of the plaintiff.

A surgeon was called in consultation who advised an immediate operation, in which advice the second physician did not concur. This surgeon was again called in consultation and sent his assistant, who likewise advised immediate operation. The second defendant not concurring in the advice, the patient was removed to the hospital of the surgeon and there operated upon for the drainage of pus. Her condition became progressively worse and it was necessary to perform a hysterectomy upon the plaintiff. She subsequently recovered and thereafter the patient and her husband instituted actions of alleged malpractice against both of the defendants.

The actions not having been commenced within two years after the cause of action had arisen, upon motion made in behalf of the defendants the complaints were dismissed on the ground that the actions were barred by the Statute of Limitations, terminating these actions in favor of the defendants.

Medical Society of the State of New York

120TH ANNUAL MEETING

March 29-April 1, 1926

House of Delegates, Monday afternoon and evening, and Tuesday morning Section meetings, Tuesday afternoon and Wednesday morning and afternoon Demonstration on Syphilis all day Thursday Annual Dinner, Tuesday Evening General Meeting, Wednesday evening

HOUSE OF DELEGATES

The regular annual meeting of the House of Delegates of the Medical Society of the State of New York will be held on Monday Afternoon, March 29, 1926, in the Ballroom of the Waldorf Astoria, New York City

NATHAN B VAN ETEN, M D *President* E ELIOT HARRIS, M D, *Speaker*
DANIEL S DOUGHERTY, M D, *Secretary*

120TH ANNUAL MEETING

The regular annual meeting of the Medical Society of the State of New York will be held on Wednesday Evening, March 31st, in the Ballroom of the Waldorf Astoria, New York City

NATHAN B VAN ETEN, M D, *President* DANIEL S DOUGHERTY, M D, *Secretary*

PROGRAM

Calling the Society to order by the President, Nathan B Van Eten, M D
Address of Welcome by the Chairman of the Committee on Arrangements, Edward R. Cuniffe, M D
Reading of the minutes of the 119th Annual Meeting by the Secretary, Daniel S Dougherty, M D
President's Address, Nathan B Van Eten, M D

ANNUAL BANQUET

The Annual Banquet will be held in the Waldorf Astoria, Tuesday evening, March 30th.

SPECIAL SYPHILIS DEMONSTRATION

The committee on scientific work of the Medical Society of the State of New York has arranged a special day, Thursday, April 1, for a demonstration of Syphilis in all its varied phases
For program, see page 167

SECTION PROGRAMS

SECTION ON MEDICINE

Chairman, L Whittington Gorham, M D, Albany
Secretary, Wardner D Ayer, M D, Syracuse
Place of Meeting, Waldorf-Astoria

Tuesday, March 30th, 2 30 P M

"Liver Function Studies," Charles S McVicar, M D, Rochester, Minn (by invitation)
Discussion

"Neuron Block for the Relief of Pain With a Report as to Its Use in Angina Pectoris," George I Swetlow, M D, Brooklyn

Discussion opened by John Wyckoff, M D, New York City

"Basic Factors in Human Hypersensitiveness," Robert A Cooke, M D, and Will C Spain, M D, New York City

Discussion opened by Aaron Brown, M D, New York City

"The Recognition of Chronic Nephritis in its Early Stages, and Consideration of Some Neglected Principles in Functional Diagnosis," Nellis B Foster, M D, New York City

Discussion opened by John A Lichty, M D, Clifton Springs

"The Clinical Result after the Long Continued Use of Insulin," John Ralston Williams, M D, Rochester

Discussion opened by Nelson G Russell, M D, Buffalo

Wednesday, March 31st, 9 30 A.M

Joint Session with Section on Surgery

"More Recent Studies Upon the Etiology of Post-Operative Pneumonitis," Allen O Whipple, M D, New York City

Discussion

"The Experimental Production of Lung Abscess," Elliott Cutler, M D, Simon A Schlueter, M D, I F Weidlein, M D, Cleveland, Ohio (by invitation)

Discussion opened by James M Hitzrot, M D, New York City

"Pulmonary Abscess and Its Treatment," (a) from the Surgical Standpoint, Adrian V S Lambert, M D, New York City, (b) from the Medical Standpoint, James A Miller, M D, New York City

Discussion opened by Howard Lilienthal, M D, and John D Kernan, M D, New York City

"Broncho-pulmonary Spirochetosis," David T Smith, M D, Ray Brook

Discussion opened by Edward R Baldwin, M D Saranac Lake

Wednesday, March 31st, 2 30 P M

Joint Session with Sections on Pediatrics and Neurology and Psychiatry

"The Vegetative Nervous System and Encephalitis with Special Reference to Personality Changes in the Young," Foster Kennedy, M D, New York City

Discussion opened by E D Friedman, M D, New York City

"The Relation of Vitamins to Disease," E V McCollum, M D, Baltimore, Md (by invitation)

"The Vitamin Value of Some Common Food-stuffs," Walter H Eddy, Ph D, New York City (by invitation)

Discussion

"A Survey of Our Present Knowledge of Tetanus and Its Treatment," Matthias Nicoll, M D, Albany

Discussion opened by John J Moorhead, M D, New York City

SECTION ON SURGERY

Chairman, Edward S Van Duyn, M D, Syracuse

Secretary, George E Beilby, M D, Albany

Place of Meeting, Waldorf-Astoria

Tuesday, March 30th, 2 30 P M

Joint Session with Section on Neurology and Psychiatry

"The Principles and Methods of Treatment of Fracture Dislocation of the Neck," Alfred S Taylor, M D, New York City

Discussion opened by Foster Kennedy, M D, New York City

"Ventriculometry (with Lantern slide demonstration)," K. Winfield Ney, M D, New York City

Discussion opened by S Philip Goodhart, M D, New York City

"Differential Section of the Trigeminal Root in the Surgical Treatment of Trifacial Neuralgia," Byron Stookey, M D, New York City

Discussion opened by Martin B Tinker, M D, Ithaca and John L Eckel, M D, Buffalo

"The Diagnosis and Localization of Brain Tumors" (with lantern slide demonstration) Walter E Dandy, M D, Baltimore, Md (by invitation)

Discussion opened by Charles A Elsberg, M D, New York City

Wednesday, March 31st, 9 30 A.M

Joint Session with Section of Medicine

"More Recent Studies Upon the Etiology of Post-Operative Pneumonitis" Allen O Whipple, M D, New York City

Discussion

"The Experimental Production of Lung Abscess," Elliott Cutler, M D, Simon A Schlueter, M D, I F Weidlein, M D, Cleveland Ohio (by invitation)

Discussion opened by James Morley Hitzrot, M D, New York City

"Pulmonary Abscess and Its Treatment" (a) from the Surgical Standpoint, Adrian V S Lambert, M D, New York City, (b) from the Medical Standpoint, James A Miller, M D, New York City

Discussion opened by Howard Lilienthal, M D, and John D Kernan, M D, New York City

"Broncho-pulmonary Spirochetosis," David T Smith, M D, Ray Brook

Discussion opened by Edward R Baldwin, M D Saranac Lake

Wednesday, March 31st, 2 30 P M

"Further Advancement in the Technique and Interpretation of Cholecystography by the Oral Method," William H Stewart, M D, New York City

Discussion opened by Lester Levyn, M D, and A H Aaron, M D, Buffalo

Medical Society of the State of New York

120TH ANNUAL MEETING

March 29-April 1, 1926

House of Delegates, Monday afternoon and evening and Tuesday morning Section meetings, Tuesday afternoon and Wednesday morning and afternoon Demonstration on Syphilis all day Thursday Annual Dinner, Tuesday Evening General Meeting, Wednesday evening

HOUSE OF DELEGATES

The regular annual meeting of the House of Delegates of the Medical Society of the State of New York will be held on Monday Afternoon, March 29, 1926, in the Ballroom of the Waldorf Astoria, New York City

NATHAN B. VAN ETEN, M.D., *President* E. ELIOT HARRIS, M.D., *Speaker*
DANIEL S. DOUGHERTY, M.D., *Secretary*

120TH ANNUAL MEETING

The regular annual meeting of the Medical Society of the State of New York will be held on Wednesday Evening, March 31st, in the Ballroom of the Waldorf Astoria, New York City

NATHAN B. VAN ETEN, M.D., *President* DANIEL S. DOUGHERTY, M.D., *Secretary*

PROGRAM

Calling the Society to order by the President, Nathan B. Van Eten, M.D.
Address of Welcome by the Chairman of the Committee on Arrangements, Edward R. Cunniffe, M.D.
Reading of the minutes of the 119th Annual Meeting by the Secretary, Daniel S. Dougherty, M.D.
President's Address, Nathan B. Van Eten, M.D.

ANNUAL BANQUET

The Annual Banquet will be held in the Waldorf Astoria, Tuesday evening, March 30th

SPECIAL SYPHILIS DEMONSTRATION

The committee on scientific work of the Medical Society of the State of New York has arranged a special day, Thursday, April 1, for a demonstration of Syphilis in all its varied phases.

Discussion by Frankwood E Williams, M D, New York City

Wednesday, March 31st, 2 30 P M

"Periodic Health Examinations," Charles S Prest, M D, Brooklyn

"Health Legislation," Paul B Brooks, M D, Albany

"Lessening the Industrial Cost of Syphilis," Benjamin J Slater, M D, Rochester

"Post Graduate Medical Education, Its Value to Public Health," Frank H Richardson, M D Brooklyn

"The Establishment of Incinerator Districts" Richard Slee, M D, Rockville Center

SPECIAL DEMONSTRATION ON SYPHILIS

Thursday Morning, April 1st

The morning session, in the ballroom of the Waldorf-Astoria, will begin at 10 o'clock with a complete clinical and pathological demonstration of every phase of syphilis from the initial sore to the terminal parietic dementia, illustrated by patients pathological specimens, X-ray pictures, moving pictures (ten machines will be in constant operation) charts instruments, drugs, etc This demonstration in twelve cubicles will continue the entire day and will be in charge of the

leading syphilographers of New York City They will be in constant attendance to demonstrate characteristic lesions, to clear up doubts on differential diagnosis and to indicate the approved lines of treatment in the different phases of this disease In short they will stand ready to answer in the light of our present knowledge all questions in regard to syphilis In a later issue of this JOURNAL all the details of this demonstration will be published

Thursday Afternoon, April 1st

2 00 P M—"What Price Syphilis?" William F Snow, M D, New York City

2 30 P M—"Syphilis from the Point of View of the Internist," Udo J Wile, M D, Ann Arbor, Mich (by invitation)

2 45 P M—"Syphilis from the Point of View of the Neuro-psychiatrist," George H Kirby, M D, New York City

3 00 P M—"Syphilis from the Point of View of the Obstetrician" Alfred C Beck, M D, Brooklyn

3 15 P M—"Syphilis from the Point of View of the Pediatrician," Isaac A Abt, M D, Chicago, Ill (by invitation)

3 30 P M—"Problems Methods and Results in the Treatment of Syphilis," John H Stokes, M D, Philadelphia, Pa (by invitation)

NEWS NOTES

SPECIAL COMMITTEE OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK TO STUDY NURSING PROBLEM

A conference has been called for the purpose of discussing the questions stated in the notice of the meeting. The answers to the first three questions we believe will contribute valuable data to our records. Free discussion of the last two questions we hope may lead to a constructive program on the nursing question which will eventually be satisfactory to all concerned. The call is as follows

February 5, 1926

The Sub-Committee on Nursing of the Medical Society of the State of New York invites you to meet with representatives of the New York State Nursing Association, to consider in conference the following questions and trusts you will be present at the Academy of Medicine, 17 West 43d Street, New York City, on Friday, February 12th, 1926, at 3 P M

(1) The doctors from many parts of the state report a shortage of bedside nurses. What is your explanation of such shortage?

(2) What opportunity is offered to graduates from other states or countries maintaining courses of training of two years and over to become qualified for registration in this State?

(3) Does the equivalent of one year High School mean approved school marks or ratings, or does it mean intelligence, character, experience, desire and fitness for nursing as determined by credentials or by the personal observation of the officials of the Training School?

(4) What is the objection (a) To a two year course in basic training of a pupil nurse who will graduate as a trained nurse and be registered as such, (b) To post graduate or special courses for those who would specialize as teachers, public health, industrial and executive nurses

(5) Would you indicate how the curriculum which warrants the asking of the following state examination questions may be modified for the purpose of training the basic trained nurse?

SOME OF THE STATE EXAMINATIONS QUESTIONS

June 27, 1922

Define a stimulant. Name (a) a heart stimulant, stating the common adult dose, (b) a respiratory stimulant, stating the common adult dose

From what source are the pituitary preparations obtained? Give the therapeutic uses of these drugs

June 26, 1923

Medical Nursing and Nursing of Children

Differentiate the symptoms of apoplexy from those of alcoholic intoxication. Give the early nursing care of a person stricken with apoplexy

Why do convalescent patients often become constipated? Mention three nursing measures that may be employed to overcome this tendency

What are the important points in the nursing treatment of a malaria patient?

May 19, 1924

Medical Nursing and Nursing of Children

State the most common causes of anemia. Give an example of (a) primary anemia, (b) secondary anemia

Describe your method of caring for a child with eczema of the face. What particular foods should be avoided in such a case?

In caring for a child with marasmus how may the nurse determine if the food given is being digested and assimilated?

Name five common and serious complications of influenza

Give the nursing measures to be used for the relief of toxemia in typhoid fever

If left to your own discretion, what nursing measures would you employ to relieve tympanites in a case of pneumonia?

Give the nursing care of a patient with cardiac dropsy

Give nursing measures for the relief of low muttering delirium of typhoid fever

Mention the most dreaded complication of measles. Mention the class of children particularly susceptible to this complication

May 21, 1924

Bacteriology and Surgery

What is meant by (a) Gram-positive, (b) acid-fast?

How are new growths classified?

What is a Colles' fracture? In a case of a Colles' fracture what would you do pending the arrival of the doctor?

Outline briefly the nursing treatment in a case of surgical shock

What is Pott's disease? How may it be corrected?

Mention some nursing points that you would consider specially important in the care of a case of cataract after operation. Mention two prominent symptoms that may occur in carcinoma of the uterus. What advice would you give a woman who had those symptoms?

Dietetics

What foods should be restricted in scarlet fever? Why? What foods may be given in scarlet fever?

What type of diet should be given when there is a superacidity of the stomach?

What foods should be avoided in such a case?

September 22, 1924

Anatomy and Physiology

State the anatomic reasons why meningitis frequently follows mastoiditis.

What physiologic conditions influence the amount of urine excreted?

May 18, 1925

Medical Nursing and the Nursing of Mental and Nervous Diseases

What are the symptoms of an acute attack of nephritis?

Define arteriosclerosis. What are its most frequent complications?

Give the symptoms of empyema. In what disease is it a complication?

Differentiate between hemorrhage and perforation in typhoid fever.

What can be done to relieve the itching of an acute eruption?

Mention some objections to the use of sedatives in psychiatric cases. What nursing measures are helpful in obviating the use of sedatives and hypnotics?

What is the cause of general paralysis?

May 19, 1925

Pediatrics

What two diseases are frequently followed by suppurative otitis media? Why is this complication liable to be very dangerous?

Differentiate between the throat symptoms of tonsillitis and those of diphtheria.

Mention some of the predisposing causes of broncho-pneumonia in children. Briefly outline nursing treatment of a severe type of pneumonia in a child.

If a child showed symptoms of suspected appendicitis, what nursing precautions should be used before the arrival of a physician?

Differentiate between the throat symptoms of tonsillitis and those of diphtheria. By what means is a positive diagnosis of diphtheria determined?

Hygiene and Sanitation and the Principles of Bacteriology

Give three causes of flat-foot. Mention two exercises for the correction of flat-foot.

May 21, 1925

Obstetric Nursing

Name three digestive disturbances of infants and state nursing measures that may be used to overcome these disturbances.

Define version, ovulation, hematoma, phlegmasia alba dolens, atelectasis.

What is your opinion regarding the licensing of midwives?

Materia Medica

State the therapeutic use of strychnin.

What change would be expected in the rate and force of the pulse after giving a dose of

(a) caffeine

(b) chloral-hydrate

(c) pituitrin

Yours very truly,

E ELIOT HARRIS,
Chairman, Sub-Committee on Nursing

AMERICAN MEDICAL ASSOCIATION, ANNUAL MEETING

The Annual Meeting of the American Medical Association will be held in Dallas, Texas, April 19 and 23, 1926. The pleasure and profit of attending the meeting will be greatly enhanced by participation in a travel tour in which a group of doctors and their wives enjoy the companionship of one another, and are relieved of the burden of attending to the details of travel and hotels. Such a trip from New York, Boston and Philadelphia is arranged by the Lifsey Tours, Inc., 527 Fifth Avenue, New York, under the supervision of a committee of physicians whose

Chairman is Dr. N. B. Van Etten, President of the Medical Society of the State of New York, and whose Secretary is Dr. D. S. Dougherty, Secretary of the State Society. The details of the trip is set forth in a folder of 24 pages which may be obtained from the Lifsey Tours.

Special cars or a train if necessary, will be at the disposal of those who take the trip. The tour will start from the Pennsylvania Station, New York, on Friday, April 16, at 4:50 P. M. and will arrive in Dallas on Sunday, April 18, at 1:40 P. M. The party will remain in Dallas

until Friday, April 23d, in order to attend the A M A meeting

Doctors from upstate New York may take a train leaving Boston at 2 00 P M on April 16, Albany at 7 49 P M, Utica at 9 46, and Syracuse at 10 57, and Cleveland at 6 00 A M on April 17

From Dallas a choice of three itineraries is offered

- 1 To the Panama Canal Zone
- 2 To Mexico City
- 3 To California

The tour to the Panama Canal Zone will start from Dallas at 5 10 P M on Friday, April 23d, and the route will be to New Orleans, to Havana, to Cristobal, and to Panama. Returning the route will be back to Cristobal, Havana, New Orleans and Atlanta, and back to New York

The cost of this complete trip including transportation from New York and back to New York will be from \$452.75 to \$575 per person, varying with the accommodations which are chosen

The tour to Mexico City will start from Dallas on Friday evening, April 23, at 8 30 o'clock, and will include San Antonio, Laredo, Monterey and San Luis Potosi. Mexico City will be reached on Monday, April 26 at 6 10 A M

Tuesday to Friday will be spent in Mexico City

The return trip will start at 8 50 A M on Saturday, May 1, and the tour will include Torreon, Ciudad Juarez, El Paso, and St. Louis, and is scheduled to arrive back in New York at 5 50 P M on Thursday, May 6

The cost of this tour from New York and back will be from \$495 to \$565 for each person

The California tour will start from Dallas on Saturday, April 24, at 1 15 P M, and will include Fort Worth, El Paso, San Diego, Los Angeles, Del Monte, San Francisco, Salt Lake City, Colorado Springs, Denver and Chicago, and will end at New York at 5 25 P M, on Monday, May 17

The cost of this tour from New York and back will be from \$505 to \$565 per person

The booklet states that passports will not be required

Arrangements may also be made for a trip directly to Dallas and return. Also the Lifsey Tours, Inc., will arrange special trips for those who desire them

The details of the tours will be handled by the Lifsey Tours, Inc., with the physicians' Committee acting in an advisory capacity

MEDICAL SOCIETY OF THE COUNTY OF MONROE

A special meeting of the Medical Society of the County of Monroe was called by Dr A G Morris, President, on the 19th of January, 1926, to consider proposed changes in the Workmen's Compensation Law. The meeting was largely attended and the members gave enthusiastic and earnest attention to Dr H P Hourigan of Buffalo, N Y, Chairman of the Special Committee of the State Society, to study this problem and draft a bill embodying desired changes in medical procedure under this act. Dr Hourigan explained in detail the provisions of the bill, drawn up under the supervision of this Committee and introduced in the Assembly by Mr Miller (Assembly No 65). Dr

William Warren Britt of Tonawanda, Chairman of the Committee on Medical Economics of the State Society, opened the discussion which was continued by a number of the members present. The adoption of the following resolution was then moved, seconded and unanimously carried

'Be It Resolved That the Medical Society of the County of Monroe, in special meeting held January 19, 1926, approve and endorse the Miller Bill (Assembly No 65), entitled "An Act to amend the Workmen's Compensation Law, in relation to the treatment and care of injured employees, and medical procedure"

MEDICAL SOCIETY COUNTY OF ONEIDA

The annual meeting was held at the Hotel Martin, Utica, January 19th, 1926

The following officers were elected for 1926 President, Dr J L Golly, Vice President, Dr E R Evans, Secretary, Dr William Hale, Jr, Treasurer, Dr Hyzer W Jones, Librarian, Dr T Wood Clarke, Censors, Dr G M Fisher, Dr W B Roemer, Dr D E Pugh, Dr H F Hubbard, Dr C E Bartlett, Delegates, Dr A Sloan, Dr G M Lewis

A gavel, presented to Dr C B Teft 18 years

ago, when he was president of the Albany Medical School Alumni in this district, was presented to the Society by the family of Dr Earl D Fuller, to whom it was given after Dr Teft's death

Dr William Warren Britt gave a talk in which he referred especially to the proposed amendment to the workmen's compensation law

Dr Sands C Maxson spoke on the possibility of heredity in cancer disease and reported a case of glioma of a child which had occurred 35 years ago

THE DAILY PRESS

THE PHYSICIANS' HOME

The campaign for raising a two million dollar endowment for The Physicians Home, Inc., at Canadea, N. Y., is receiving considerable attention from the newspapers. The Herald Tribune, November 24, described the dinner given in the Waldorf on November 23rd, for the purpose of starting the campaign. The column called "The Lantern" in the same issue carried a semi-humorous suggestion by Edward Hope which, however, is a strong argument for the Home, for it pictures a physician inmate in a human light. The account reads:

"We are in favor of the drive, inaugurated last night, to raise \$2,000,000 for a home for aged and poverty stricken physicians. Our only question is whether two million is enough. Will that sum provide all the comforts and satisfactions to which a retired physician is entitled as a reward for honorable service?"

We advocate adding a million or two to provide special features, planned expressly for physicians.

Each room, for instance, must have a fireplace and before it the most comfortable of arm chairs. Beside the arm chair there shall be a shelf of books, selected by the occupant of the room. On cold, blustery winter evenings, then, the old doctors may make themselves perfectly comfortable and settle down to browse over their favorite volumes.

And now comes the special service.

After the ancient doctor has sat in peace for twenty minutes, a telephone at his side will ring and a trembling, hurried voice will say:

"Is this the doctor?"

"Yes."

"Doc, my baby's sick. I live eight miles northeast of town on the Smithville Road. I got to have you right away, Doc. Can you hitch up and come?"

This is the supreme moment. The ancient inmate of the home will settle himself deeper into his chair. He will place his slippers on the fender and wiggle his toes in the warmth of the blazing logs. He will clear his throat.

"I'm sorry," he will say quietly. "I have retired from active practice. I'll send a young fellow. I have here who is a specialist on babies."

Perhaps we are wrong. Perhaps it would break an old physician's heart to feel himself out of the fight, to send a young fellow, a specialist.

If the home should inaugurate such a practice as we have outlined and provide the necessary corps of specialists, probably the old doctors would forget all about it and kick off their slippers and say:

"All right. I'll be right over."

But surely there could be no harm in letting each of the old fellows take up, at last, the specialty he has been meaning for forty years to get at.

And, if there is room in the home for the physicians' wives, it would be a nice opportunity to renew an acquaintance that practically left off when the practice got so big.

If it were possible to raise an endowment large enough to pay every physician his back bills there would, of course, be no need of building a home at all."

RAISING THE DEAD

The Herald Tribune, December 19, gave a conspicuous space to a short notice of an address by Professor Yondell Henderson, of Yale University, on December 18, before the Dental Board of the United Kingdom in London. In the course of his address, Dr. Henderson gave an explanation of the miracle ascribed to Elisha by which the prophet raised from the dead the son of the Shumanite woman. The account reads:

"The child probably was in a coma as a result of eating poppies in the fields. Elisha breathed carbon dioxide, which is exhaled by all human beings, into the child, he explained, and recent experiments show that carbon dioxide, used with anaesthetics, allows greater control of breathing and speedier return from anaesthetics. He held this use of carbon dioxide would be a great advance in surgery."

Dr. Henderson is an authority on gas poisoning, and his researches into the nature of carbon monoxide poisoning and the effects of the inhalation of carbon dioxide with oxygen, enable any physician to repeat the seeming miracle on a person who is in deep coma due to carbon monoxide inhalation, or drowning, or electrocution.

In explaining the miracles of raising the dead one must consider what is meant by the word death. The American Indians say that when a man has a vision or vivid dream, he really dies, and his spirit leaves the body for a time and visits the happy hunting grounds. To the Eastern people, any deep coma is death, and even a modern scientist is sometimes unable to determine whether or not life is present, except by his success or failure in

efforts of resuscitation. Only recently a prominent man was quoted by the newspapers as saying that his daughter had spent four days in Heaven and had been restored by the efforts of her physician. Modern physicians are gratified that they are able to accomplish deeds of restoration which formerly seemed so impossible that they were called miracles.

A YEAR TO FIGHT DIPHTHERIA

This is the title of an editorial in the January seventh issue of the New York Sun. We are reproducing the editorial as an example of an excellent form of lay publicity on a medical topic.

"Diphtheria is a disease medical science has practically conquered. The physician can determine what child is immune from it and what child is liable to be attacked by it. He can administer a serum immunizing those who are disclosed to be subject to it.

"All that is needed to translate these protective and preventive possibilities into a great and lasting boon to humanity is popular understanding of the virtues of the serum and public recognition of the simplicity and safety with which it may be used. The public is slow to take advantage of such advances in science. It can be induced to use them only by intensive instruction long continued and intelligently directed. This year it is to have such instruction in the needlessness of illness, suffering and death from diphtheria.

"The educational course will be directed by the State Department of Health. It will utilize every agency of publicity the department can command. Commissioner Nicoll has issued a proclamation calling on all health officers to help. He wants the active assistance of physicians, parents, State, county and municipal officials, teachers, preachers, whoever has responsibility for children or can command their attention. He has opened a campaign for eradication of diphtheria, to accomplish its object in twelve months, and thus rid infancy of one of its worst menaces.

"None but the callous and the ignorant will refuse to join this movement. It means innocent lives saved, children made safe, disease balked. If diphtheria is not eradicated from New York State this year it will mean that the people are too careless to safeguard their infants from death."

President, Dr. J. L. Goss

NOISE AND HEALTH
is affected by noise, especially
necessary, it, Del's health officer. The
to evade a decision, Dr. Cng with two uncer-

tain quantities, first, the measurement of the noise itself, and second, the estimations of the susceptibility of the patient. The New York Herald-Tribune, January 17, reports the efforts of Dr. E. E. Free, Scientific Editor of "Forum", to answer the question, "How Noisy is New York?"

Dr. Free devised an instrument to measure the intensity of noise. The "sound unit" that adopted was just twice as much noise as enters the ear when there is no particular cause of noise or when the hum of a great city is reduced to its lowest level. Ten units are a loud noise, and seventy units are almost deafening.

The doctor reported that the noisiest place he found was at Sixth Avenue and Thirty-fourth Street, because of the combined rumble of the elevated and surface lines, and the subway and street traffic. There the record was 50 sound units.

Starting on Fifth Avenue, the noise on Washington Square was mild, 20 units. At 23rd Street where crosstown surface cars and those of Broadway crossed Fifth Avenue, the noise was 35 units, and at 42nd Street, the noisiest corner on Fifth Avenue, it was 40 units. The quietest place in this city was in the midst of Greenwich Village.

Most of the noise of the city arises from its traffic. Human beings make virtually no noise. It was only in the lower East Side that there was any discernable noise traceable to human voices. There people are so thickly packed together that their voices alone registered from five to ten units of sound.

The noise of the motor trucks is greater than that of the elevated railroad. The next loudest noise makers were the riveters on steel constructions, horns on automobile trucks, pneumatic drills, and the Fire Department apparatus.

The survey of city noise was undertaken for the purpose of studying its effect on the physical and mental health of human beings. The conclusion was that, however irritating a noise may be, its damage is not serious and possibly is so small as to be negligible. City noise is street noise. If one keeps away from the street, he can be practically free from the annoyance of noise.

The estimation of the effects of noises is complicated by the fact that a person readily becomes accustomed to a continuous noise, though it be annoying at first. One even becomes accustomed to the noises such as those of the elevated railroads, which come only at intervals, provided they are monotonous in their recurrence. What are called unnecessary noises are annoying because they are strange. Probably, if a noise recurs regularly and is heard day after day, its unpleasantness soon ceases and its very existence is unnoticed.

BOOKS RECEIVED

- THE AMERICAN ILLUSTRATED MEDICAL DICTIONARY A New and Complete Dictionary of the Terms Used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, Nursing, Veterinary Science, Biology, Medical Biography, etc., with the Pronunciation, Derivation, and Definition, including much Collateral Information of an Encyclopedic Character Edition revised and enlarged. - NON-SURGICAL TREATMENT OF DISEASES OF THE MOUTH, THROAT, NOSE, EAR AND EYE. By THOMAS H. ODENEAL, M.D. Otolologist, Rhinologist Laryngologist and Ophthalmologist to the Beyer Hospital Corporation, Beverly, Mass. P Blakiston's Son & Company, Philadelphia, Pa. Price \$4.00

TEXT-BOOK OF HUMAN PHYSIOLOGY INCLUDING A SECTION ON PHYSIOLOGIC APPARATUS By ALBERT P BRUBAKER, A.M., M.D., LL.D. Eighth edition, revised and enlarged. Octavo of 853 pages with 367 illustrations. Phila., P. Blakiston's Son and Co., 1925. Cloth, \$5.00.

This text-book has enjoyed considerable popularity among medical students and teachers for many years, and deservedly. The Eighth Edition includes many revisions and enlargements, incorporating new material and new diagrams. The result is a comprehensive presentation of the essential facts of Physiology for the student and practitioner of medicine, in a form admirably characterized by brevity and lucidity.

Among the subjects which have been revised are, notably, those of the metabolism of fat, the relation of the pancreas and its internal secretion, insulin, to the metabolism of the carbo-hydrates, the electro-cardiogram, and the indirect method of determining heat production. New diagrams of the innervation of the heart and of the bladder, the acoustic tracts, the facial nerve and its associated nerve tracts will be found to be helpful.

G. H. R.

METHODS IN SURGERY Used in the Surgical Divisions of Barnes Hospital, St. Louis Children's Hospital and Washington University Dispensary. By GLOVER H. COPIER, M.D. The C. V. Mosby Co., St. Louis, 1925. Price, \$3.00.

This book is a compend of the methods, routines, suggestions and instructions prepared primarily for the guidance of the house officers and students of Washington University School of Medicine, working in surgical divisions of the Barnes Hospital, the St. Louis Children's Hospital, and the Washington University Dispensary. It includes outlines for case history taking, preoperative and postoperative care of patients, diet lists, etc.

Such a compend encourages thoroughness and uniformity in the examination and care of patients, and is a handy reference book for an interne staff of such institutions as have adopted the technique and the routine described. There are included references to subjects which concern the relations between the visiting and interne staffs and the administrative and executive sides of a general hospital. Outlines of technique and routine such as are found in this book would serve a useful purpose even to the general practitioner, in helping him to avoid those errors of omission in diagnosis and treatment which are the penalty of a busy general practice.

J. R.

NEWER METHODS OF OPHTHALMIC PLASTIC SURGERY By EDMUND B. SPAETH, M.D., F.A.C.S. Octavo of 258 pages with 168 illustrations. Philadelphia, P. Blakiston's Son and Co., 1925. Cloth, \$5.00.

As the title implies this book deals with the newer methods of plastic surgery, many of which were used during and since the World War.

The Foreword by Dr. W. H. Wilmer is followed by the text written in two parts.

Part One—Deals with the general principles of Plastic Surgery. This is subdivided into four chapters.

Chapter I. General Operative Technique, Anæsthesia, Routine Operative Regime, etc.

Chapter II. Skin Grafts, the various types used.

Chapter III. Flaps, pedunculated, tubulated, etc.

Chapter IV. Appliances for Pressure, Prostheses, etc.

In Part II the author dealing more especially with

the ophthalmic aspect, arranges his text in four chapters and in appendix.

In Chapter V the subject of Ectropion, Entropion and other lid conditions are considered.

Chapter VI. Discusses lid conditions as Canthotomy and Canthoplasties, Tarsorrhaphies, Deformities of the lid margins, etc.

Chapter VII. Relates to Symblepharon, Restoration of the Cul-de-sac, Reconstruction and Restoration of the Lids and Orbital Socket.

Chapter VIII. Physiotherapy and Medication in its application to Ophthalmic Plastic Surgery.

In the Appendix is a rather complete Bibliography.

The book is well written, clear and concise and is illustrated with 170 selected cuts.

The author, as he states in his introduction, does not describe the many well known methods for the correction of ocular defects, but rather describes his and other newer methods. The illustrated cases and the procedure followed are most instructive.

No two cases are alike in this branch of Surgery and the operator must therefore study and then select the best procedure in each case. This book would help much in suggesting ways and means to obtain the best results.

On Tarsus Resections the operation advised by Dr. Wheeler is described and the others only referred to. The author takes a firm stand against paraffin injections, also advises a Mules glass ball implanted after enucleation.

In the 250 odd pages the material is condensed and arranged so as to be most helpful and the references make further study easily available. Not only the Oculist but the General Surgeon will find this book most valuable.

We endorse most heartily Dr. Wilmer's statement at the end of his Foreword, namely:

"In this addition to scientific literature, the author has made an important contribution to ophthalmic surgery and supplied a real ophthalmic need."

J. H. O.

PYE'S SURGICAL HANDICRAFT A Manual of Surgical Manipulations, Minor Surgery, and other Matters connected with the work of house surgeons and surgical dressers. Edited and largely rewritten by W. H. CLAYTON-GREENE, C.B.E., B.A., M.B., B.C. (Camb.), F.R.C.S. (Eng.) Ninth Edition, fully revised. Illustrations. *Vel de minimis curat chirurgicus*. William Wood and Co., New York, 1924. Price, \$7.00.

This is the ninth edition of a book originally published by Walter Pye, but which has since been rewritten by W. H. Clayton-Greene.

The purpose of the original author to "present the details of surgical work as it appears from the point of view of the house-surgeon," has been followed out pretty closely. The young surgeon will find a mass of valuable information, and many useful hints that the average text-book on surgery does not supply. This is especially true of the treatment of emergency conditions, such as accidental wounds, hemorrhage, the principles of the use of splints, and their varieties, the immediate treatment of fractures, &c. &c.

There is a good deal of material that is entirely unnecessary and which leaves a rather poor impression. The detailed description of the Wassermann reaction, the examination of urine, and the principles of the X-ray apparatus, are entirely out of place. These however, are minor points as compared with the excellent merits of the rest of the text.

THE TREATMENT OF CERTAIN CARDIAC EMERGENCIES

By HAROLD E B PARDEE, M D

NEW YORK CITY

I THOUGHT that it might be interesting to review with you the treatment of certain emergencies which have a common cause in cardiac disease. Some of these conditions are very serious, others are merely startling or alarming to the patient. Anyone of them may serve to call the doctor out at uncomfortable hours of day or night, and so may be properly spoken of as an emergency.

One of the most alarming conditions that a physician is called upon to meet is an attack of acute oedema of the lungs. The patient is sitting up in bed, weak and exhausted, restless, gasping for air, looking as though each breath were going to be his last. He usually raises pinkish frothy sputum and examination will reveal that the lungs are full of the numerous fine rales and ronchi that are typical of pulmonary oedema. You may wonder, perhaps, that I have mentioned pulmonary oedema as a cardiac emergency, but you will realize on second thought, I am sure, that it is always due to cardiac failure and so belongs quite rightly in this discussion.

Oedema of the lungs may come on quite acutely or it may develop rather gradually during the course of a few hours in a patient who has some other sickness. The paroxysmal form occurs in the course of chronic hypertension and in these patients the blood pressure will be found well above 200 mm. It may occur in the course of arteriosclerosis of the coronary arteries, sometimes being the result of coronary thrombosis with cardiac infarction. Sometimes it seems likely that it is not due to thrombosis but to a temporary functional failure of the heart. In these coronary cases the blood pressure is low, 100 mm or less, or, if it has been previously elevated, is lower than its accustomed level and probably not above 150 or 160 mm. Examination of the heart in such a case may reveal no abnormality, except a faintness of the heart sounds. Neither

enlargement nor murmurs need be present, though occasionally either or both will be found.

Oedema of the lungs may occur in the course of pneumonia, but here we must make a sharp distinction between oedema with its many fine crackling rales and the condition found when there is much unexpelled mucus in the bronchial tubes and many coarse and fine ronchi or sonorous rales are heard.

Oedema of the lungs may sometimes be the result of a period of cardiac overstrain in a patient who already has valvular disease or chronic myocardial changes. During labor, a woman with heart disease will occasionally develop an acute form of oedema of the lungs. Sometimes a person with myocardial changes will bring on oedema of the lungs by some unusual effort, perhaps lifting a heavy weight, perhaps an unaccustomed more prolonged exertion. Not infrequently the effort of walking up a long hill or against a strong wind will be the cause of an attack. This may sometimes be the first sign of myocardial defect, though the patient will usually on careful questioning admit to having had some unusual dyspnea or precordial discomfort on exertion for a time previous to the attack.

The treatment of oedema of the lungs, whatever its cause, demands rest in a comfortable position, an easy chair is usually better than bed—and a hypodermic of $\frac{1}{4}$ grain of morphine sulphate and 1-50 grain of atropine sulphate. For further treatment, we must now consider both the etiology and the condition of the patient. If the blood pressure is very high—above 200—a hypodermic of 1-50 grain of nitroglycerine may work a magic change, reducing the blood pressure and relieving the strain upon the heart. In patients without the hypertension etiology nitroglycerine does no good.

If the veins in the patient's neck are found to be distended with blood, even when he is sitting erect in a chair, it indicates that there is a considerable degree of back pressure failure and overdistension of the heart with blood. The

veins are connected directly to the right auricle and so the pressure in them may be taken as an indication of the pressure in the right auricle. When the heart fails in its function of pumping the blood this accumulates in the veins and causes them to be over-distended. Thus we may measure the degree of cardiac failure by the height to which the veins must be raised before they empty. If we observe the veins at the bend of the elbow and gradually raise the arm from its natural position out to the side and upward we will find that at a certain level the vein seems to be no longer distended. This level measures the degree of back pressure in the right heart. Normally the veins at the bend of the elbow will collapse when raised to the level of the second rib, anything further than this indicating an abnormal pressure within the vein. If we must raise the vein to above the level of the clavicle it indicates a rise of venous pressure which is so great as to be harmful to the cardiac function.

Phlebotomy is the best means to relieve this. Blood should be drawn until the veins of the neck are no longer distended. It may take only 2 or 3 ounces to do this or perhaps 5 or 10 ounces. There is nothing to be gained by taking more than an amount that will relieve the congestion but we must take at least enough to do this.

If there is much cyanosis and if the above measures do not promptly relieve it, oxygen inhalation should be used. This is always advisable with pneumonia patients. The theoretical ideal for oxygen inhalation is a mask which may be placed over the face or a mouth-piece, to insert in the mouth similar to that which is used in the gas mask. These things are often not well tolerated by patients who are very short of breath, so that it is often necessary to have some other means of administering oxygen. The old familiar funnel on the end of a rubber tube has been frequently shown to have very little avail in raising the oxygen concentration of the patient's inhaled air. Each expiration blows the funnel empty of oxygen so that the inspiration is practically from room air. The most satisfactory method for an emergency is to direct the stream of oxygen from the rubber tube into the patient's nose or mouth, whichever he is using for breathing. For more prolonged use a bed tent consisting of half barrel hoops covered with a transparent rubberized silk should be placed over the patient's head and shoulders and the oxygen delivered beneath this. If it is allowed to run in at the rate of about one or two liters per minute it will produce a satisfactory concentration of oxygen beneath the improvised tent. Specially purified medical oxygen is not necessary for this purpose. The ordinary commercial oxygen is much cheaper and quite as satisfactory.

Digitalis is indicated if the patient has valvular disease or myocardial disease, but in the purely

hypertension cases I see no reason for it. Their heart is normal, and if relieved of the strain of the hypertension will recover promptly enough for itself. Digitalis will be given differently depending upon whether the patient has received digitalis or any of its allies at any time within the previous two weeks.

A patient with oedema of the lungs who has not had any digitalis within two weeks may be given a large intravenous dose. It has been found recently that the generally administered doses of the intravenous digitalis preparations are much too small. One or two ampules—15 to 20 minims of digitan solution or digifolin or digalin is so small a dose as to be practically useless.

In working with digitalis two things have been found to give an early indication of digitalis effect. These are a slowing of the ventricles when auricular fibrillation is present, and a diminution in the height of the T wave of the electrocardiogram. Both of these changes take place with an amount of digitalis much less than needed to produce the therapeutic effect. It has been found that one or two ampules of these drugs is less than the amount which will affect the T wave of the electrocardiogram or slow the heart rate with auricular fibrillation. To produce the slightest appreciable effect at least three ampules are needed. To produce a prompt and marked effect we need an amount equal to 1 minim of the solution per pound of the patient's weight—8 ampules for a patient of 120 lbs and 10 ampules for a patient of 150 lbs. It should be given slowly over a period of 2 or 3 minutes so that it may be well mixed with the patient's blood and not arrive in the heart all at one time.

This may seem an impossible dose to you, but I have demonstrated to my own satisfaction at least that these preparations are no stronger than a good tincture of digitalis and that they do not produce any demonstrable effects in doses of less than three or four ampules, 25 or 30 minims per pound of body weight of the patient. If tincture of digitalis is given by mouth in the same dose—1 minim per pound of body weight—the first demonstrable effects will appear in from 2 to 4 hours and the maximum effect of the dose will not be reached until from 6 to 10 hours after administration. This is much too late to be useful for an emergency. The intravenous administration of this dose of the digitalis preparations does not produce instant effect but does something by 15 minutes, with the maximum effect between 1 and 2 hours after administration.

For patients who have been receiving digitalis within the past of 2 weeks it is very difficult to decide upon the intravenous dose. We must err on the side of giving too little rather than too much and 30 or 45 minim doses are proper to be repeated after 2 hours if it seems necessary.

I cannot leave the subject of intravenous digitalis without a mention of *ovabian*, the gamma strophanthin. This drug is said to act very quickly and should be given in a half milligram dose to a patient who has not had any digitalis previously. It should not be given at all to one who has already been taking digitalis, for the therapeutic and toxic doses are so close that dangerous poisoning may result. We know that definite effects are produced by a half hour after administration, but though it is generally credited to act quicker than digitalis yet experimental proof of this has not been published.

A word about the use of adrenalin in these cases. It is often given by physicians for these attacks because of the patient's weak pulse and low blood pressure. It seems to me to be absolutely contra-indicated. The best way to strengthen the pulse and raise the blood pressure should be to help the heart to pump out of the blood coming to it, and yet many physicians have told me of recoveries following the use of adrenalin and attributed by them to its use.

Another cardiac emergency that the physician meets occasionally is due to thrombosis of a branch of the coronary arteries with infarction of an area of the heart muscle. If the patient does not die almost instantly of this, the picture will be one of profound shock with almost imperceptible pulse, pale ashy grey skin and profuse perspiration. There may be vomiting or nausea or much eructation of gas. There may be no dyspnoea, or, if many rales develop in the lungs, dyspnoea may be slight or moderate. The only sensation may be an oppression in the lower anterior chest, or there may be precordial pain of any degree up to the most severe pain with wide radiation—typical angina pectoris.

For these attacks, morphine and atropine should be given by hypodermic in the doses mentioned and the morphine repeated in 15 or 20 minutes if the first dose does not quiet the patient and give relief from the discomfort. These patients are best in bed. They do not usually have the orthopnea that accompanied pulmonary oedema. Adrenalin is bad here, too, I believe, though it is sometimes given because of the weak pulse. This weak pulse is in part a life-saving measure. To raise the arterial pressure too much might stop the circulation, for the damaged heart cannot eject the blood against much resistance. Nitroglycerine is not indicated for the blood pressure is already so low that further reduction would be harmful. Absolute rest is all we can do to tide over this emergency until the heart itself can recover its strength. Relatively slight exertions, such as getting in or out of bed, can easily overstrain the weakened heart, and the patient should not be moved from one place to another for at least several hours

after the attack. There is great danger of sudden death at this time.

Another type of cardiac emergency not usually so serious as those just discussed is the severe attack of precordial pain. The pain may be due to coronary narrowing, or to aortitis, or to the occurrence of many premature beats in a person with a neurasthenic hypersensibility. Sometimes tobacco will cause precordial pain by producing arrhythmia and coincidentally raising the threshold of sensibility. Pains of many sorts and varied grades of intensity are produced by these things. Though the pain is sometimes only slight, yet at other times or in other patients there may be a pain that is so severe and radiates so widely, a typical angina pectoris, that the patient feels he is in imminent danger.

The situation of the pain helps us somewhat with the diagnosis, but we must carefully distinguish between the site of the pain itself and the distribution of its radiation. With any of these causes the radiation may be much the same, across the chest, about the apex beat, to the left shoulder, the left arm, the left side of the neck, or perhaps to corresponding places on the right side, or to both sides. This radiation is unimportant, but the seat of the pain itself, if retrosternal and below the level of the third rib, is indicative of a coronary etiology, if retrosternal and above the third rib of aortitis, and if about the region of the apex beat indicates that the cause is less likely to be organic disease of the heart than an abnormal sensibility with or without the complication of arrhythmia or tobacco.

Treatment for the patients with coronary disease or aortitis consists of rest and nitroglycerine. Nitroglycerine may be given as a tablet to be dissolved in the mouth. For severe attacks, the dose should be 1-100 grain, though 1-200 grain is usually enough. Amylnitrate by inhalation may serve better in some cases, but the severe headache that may follow makes it unsatisfactory if it must be given often. Morphine is not necessary for the pain and has no beneficial effect unless the patient is very restless and cannot be quieted by other means. The treatment of the causal condition is important with these patients so that a recurrence of the attack may be prevented. To avoid overexertion and the eating of large meals, to regulate the bowels so that stasis does not occur, to take diuretin if the cause is coronary disease and to have thorough antiluetic treatment if there is luetic aortitis, these are the chief lines to be followed.

When the pain is due to a combination of neurotic hypersensibility with arrhythmia or some form of heart disease, the best treatment for the attack is aromatic spirits of ammonia or a fair-sized dose of bromide, say 30 grains. To prevent recurrence with these patients demands the greatest care. They must be relieved of nervous

veins are connected directly to the right auricle and so the pressure in them may be taken as an indication of the pressure in the right auricle. When the heart fails in its function of pumping the blood this accumulates in the veins and causes them to be over-distended. Thus we may measure the degree of cardiac failure by the height to which the veins must be raised before they empty. If we observe the veins at the bend of the elbow and gradually raise the arm from its natural position out to the side and upward we will find that at a certain level the vein seems to be no longer distended. This level measures the degree of back pressure in the right heart. Normally the veins at the bend of the elbow will collapse when raised to the level of the second rib, anything further than this indicating an abnormal pressure within the vein. If we must raise the vein to above the level of the clavicle it indicates a rise of venous pressure which is so great as to be harmful to the cardiac function.

Phlebotomy is the best means to relieve this. Blood should be drawn until the veins of the neck are no longer distended. It may take only 2 or 3 ounces to do this or perhaps 5 or 10 ounces. There is nothing to be gained by taking more than an amount that will relieve the congestion but we must take at least enough to do this.

If there is much cyanosis and if the above measures do not promptly relieve it, oxygen inhalation should be used. This is always advisable with pneumonia patients. The theoretical ideal for oxygen inhalation is a mask which may be placed over the face or a mouth-piece, to insert in the mouth similar to that which is used in the gas mask. These things are often not well tolerated by patients who are very short of breath, so that it is often necessary to have some other means of administering oxygen. The old familiar funnel on the end of a rubber tube has been frequently shown to have very little avail in raising the oxygen concentration of the patient's inhaled air. Each expiration blows the funnel empty of oxygen so that the inspiration is practically from room air. The most satisfactory method for an emergency is to direct the stream of oxygen from the rubber tube into the patient's nose or mouth, whichever he is using for breathing. For more prolonged use a bed tent consisting of half barrel hoops covered with a transparent rubberized silk should be placed over the patient's head and shoulders and the oxygen delivered beneath this. If it is allowed to run in at the rate of about one or two liters per minute it will produce a satisfactory concentration of oxygen beneath the improvised tent. Specially purified medical oxygen is not necessary for this purpose. The ordinary commercial oxygen is much cheaper and quite as satisfactory.

Digitalis is indicated if the patient has valvular disease or myocardial disease, but in the purely

hypertension cases I see no reason for it. Their heart is normal, and if relieved of the strain of the hypertension will recover promptly enough for itself. Digitalis will be given differently depending upon whether the patient has received digitalis or any of its allies at any time within the previous two weeks.

A patient with oedema of the lungs who has not had any digitalis within two weeks may be given a large intravenous dose. It has been found recently that the generally administered doses of the intravenous digitalis preparations are much too small. One or two ampules—15 to 20 minims of digitan solution or digitolin or digalin is so small a dose as to be practically useless.

In working with digitalis two things have been found to give an early indication of digitalis effect. These are a slowing of the ventricles when auricular fibrillation is present, and a diminution in the height of the T wave of the electrocardiogram. Both of these changes take place with an amount of digitalis much less than needed to produce the therapeutic effect. It has been found that one or two ampules of these drugs is less than the amount which will affect the T wave of the electrocardiogram or slow the heart rate with auricular fibrillation. To produce the slightest appreciable effect at least three ampules are needed. To produce a prompt and marked effect we need an amount equal to 1 minim of the solution per pound of the patient's weight—8 ampules for a patient of 120 lbs and 10 ampules for a patient of 150 lbs. It should be given slowly over a period of 2 or 3 minutes so that it may be well mixed with the patient's blood and not arrive in the heart all at one time.

This may seem an impossible dose to you, but I have demonstrated to my own satisfaction at least that these preparations are no stronger than a good tincture of digitalis and that they do not produce any demonstrable effects in doses of less than three or four ampules, .25 or 30 minims per pound of body weight of the patient. If tincture of digitalis is given by mouth in the same dose—1 minim per pound of body weight—the first demonstrable effects will appear in from 2 to 4 hours and the maximum effect of the dose will not be reached until from 6 to 10 hours after administration. This is much too late to be useful for an emergency. The intravenous administration of this dose of the digitalis preparations does not produce instant effect but does something by 15 minutes, with the maximum effect between 1 and 2 hours after administration.

For patients who have been receiving digitalis within the past of 2 weeks it is very difficult to decide upon the intravenous dose. We must err on the side of giving too little rather than too much and 30 or 45 minim doses are proper to be repeated after 2 hours if it seems necessary.

FERTILITY AND HEALTH*

By DONALD MACOMBER, M.D.,

BOSTON, MASS

Fertility may be defined as a function of the reproductive organs, just as digestion is that of the stomach and intestines. The degree of fertility of a given individual depends upon two general considerations. One is the racial inheritance as to fertility, and the other those environmental influences to which the individual is exposed and which may tend to lower that particular fertility. With the social conditions under which we live, it is not possible as yet to breed strains of human beings for high fertility or other desirable characteristics, but the very fact that we are at present powerless to control the optimum inheritable fertility makes it all the more important to understand and control the environmental influences which seem to be producing an ever-increasing amount of sterility among the very elements of our population which it is most desirable to perpetuate. It has seemed important, therefore, to analyze as far as possible the various factors in the environment which are active in the production of reduced fertility.

In the first place, it is obvious that, just as with animals, the individual will be more susceptible to influences during the growth period, but due to the greater length of this period and the more complicated development that has to take place during it, there will be an even greater percentage of failures, or partial failures, in the human being than in any species of animal. It will be necessary, therefore to subdivide this period of growth much more minutely than would be the case with a similar study of animal development and growth in general.

It is unlikely that we shall find much evidence that failures of development during intra-uterine life play any important role in the lowering of fertility. Malnutrition in infancy also will probably prove unimportant in this regard. Beyond this stage, however, the general health and growth will be of increasing importance. This is particularly true of body mechanics—posture etc—and the formation of good health habits which lay the necessary foundation on which the rapid and complicated development of adolescence must rest. It must be understood that mental as well as physical habits are important.

With the onset of puberty itself and the beginning of menstruation we are more likely to encounter deviations from normal growth and development and if these are neglected permanent disabilities may result. The changes which take place during the few years of adolescence in

which the child is converted into a woman are enormous. They constitute a most serious strain to which the growing girl is subjected. Consider for a moment the extent of these changes. They may be grouped under three headings. First, there is a marked period of physical growth in height and weight, then there are those changes, both external and internal in the reproductive organs, whereby they pass from an infantile inactive state to the full size and activity of functioning womanhood, and, finally, those intellectual, emotional and social changes which characterize the transition from the child mind to that of the adult woman. Is it any wonder that mismanagement at this time may cause partial or complete failures of function later in life? One cannot help feeling that a modicum of the care exercised in the management of animal breeding would prevent a great deal of the low fertility we find so prevalent in the complicated life of the the present day.

In pursuing our inquiry into the conditions in the life of the woman for possible factors that may lower fertility, we find two other periods of stress in either of which trouble may appear. I refer to early married life and the actual bearing of children. In the former bad habits and lack of knowledge of the laws of hygiene may lead to serious chronic congestions. Chronic congestion always lowers fertility in itself, but is chiefly harmful because of the increased susceptibility to infection which it causes. Many cases of endocervicitis and of endometritis or salpingitis owe their presence to the ignorance of young married people. It is possible that non-function of the ovaries—at least as far as their oögenic action is concerned—may have a similar cause. There is still another frequent cause for the development of congestion in the woman, and that is the practise of unphysiologic methods of preventing conception. Discussion of this important subject would carry us too far afield at this time, suffice it to say that many cases of permanent sterility undoubtedly owe their origin to errors of this kind.

We have now sketched the dangers to which the woman is particularly liable during adolescence and early married life. It remains to add a word about the dangers to fertility inherent in the bearing of children. There are two ways in which pregnancy and parturition may reduce an otherwise normal fertility. One acts directly upon the constitution of the woman and is brought about by the failure of a poor vitality to meet the strains which motherhood imposes; the other is more mechanical in origin and de-

* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse May 12 1925

stram, must have sufficient rest and careful regulation of the bowels. Taking some mild sedative continuously for a while and receiving definite reassurance of the harmlessness of the attack will each do its part toward effecting a cure. They are difficult cases though, and we cannot expect them to recover promptly.

Paroxysmal attacks of rapid heart action are very distressing to the patient and so constitute another sort of emergency. The heart feels as if it were fluttering or spinning like a top or racing and the abrupt onset and cessation of the attacks is easily appreciated by the patient. We must distinguish between these attacks and simple tachycardia, which does not start or stop abruptly and which is due to a different sort of cardiac mechanism.

Paroxysms of tachycardia are due to over-irritability of a focus in the heart muscle so that it initiates a rapid series of beats. The focus may be in the auricles, ventricles or auriculo-ventricular node, but in each case the result is a rapid, *regular* heart beat. Auricular flutter may also occur in a paroxysmal form and result in a rapid regular beat which is practically impossible to tell from the sort of tachycardia just mentioned unless an electrocardiogram can be obtained. Auricular fibrillation may occur in a paroxysmal form and cause a very rapid heart rate which is *irregular*. By this sign it is easy to distinguish from the other paroxysms of rapid heart action.

Attacks of paroxysmal tachycardia may sometimes be stopped abruptly by pressure upon the vagus nerve in the neck. It is somewhat of a trick to press upon the vagus, as it lies deeply in the neck in the angle between the larynx and the vertebral muscles. It is firmly bound within the carotid sheath, however, and this is the key to its location—behind and mesial to the carotid artery. It helps greatly to have the patient lying on his back with the head in a position to relax the sterno-mastoid muscles, and turned slightly away from the side you are pressing upon. The thumb is better than the fingers for this purpose, using the left thumb for the right vagus, and vice versa, pressing it in mesial to the carotid at the point just below the hyoid bone, where the artery is most superficial. When you are certain that your thumb is mesial to the artery so that it will not slip away when you press upon it, then press directly backward, catching the artery between your thumb and the vertebral muscles. This presses upon the vagus nerve and the pressure does not need to be maintained for more than one or two seconds to produce an effect—if one can be produced. A normally beating heart will always be slowed by this procedure if you actually succeed in pressing the vagus nerve. When paroxysmal tachycardia is present this is often stopped abruptly, the heart pausing

for a second or two and then resuming, somewhat irregularly at first, and then with a normal rhythm. Sometimes the right vagus sometimes the left will be most effective so it is best to press upon first one and then the other until the desired effect is obtained, trying three or four times on each side. If neither is successful, then the induction of vomiting should be tried, using ipecac or apomorphine. If this does not succeed, morphine sulphate by hypo $\frac{1}{3}$ to $\frac{1}{2}$ grain, depending upon the weight of the patient, should be used. I would caution against using this directly after apomorphine, because of the danger of respiratory depression by the summated effects of these two drugs.

Occasionally, all of these methods will fail, and when they do we must fall back upon digitalis. Start with a single dose of the tincture equal to one minim per pound of body weight, given by mouth in three or four ounces of water. If this does not slow the heart before ten hours, give 30 minims of the tincture every eight hours day and night until the heart rhythm is affected or until vomiting appears.

Whenever under this treatment a previously regular rhythm of about 150 per minute first becomes irregular and then becomes regular at exactly half of its former rate, we are probably dealing with auricular flutter.

Paroxysmal rapid heart due to auricular fibrillation should be treated with digitalis as outlined above. If, however, the attack has only been in progress for an hour or so, it is safe to use quinidine sulphate, giving 10 grains at once, and giving five grains after four hours if the first has not stopped the fibrillation. If fibrillation is still present four hours after the second dose, then I would give digitalis as just described. It is not well to continue quinidine with these patients as you would when treating a patient with long-standing fibrillation, for I feel that it is better, if the first two doses fail, to promptly slow the heart rate with digitalis and save the patient from the possibility of cardiac failure due to the long continued rapid beating.

In closing, I think it important to stress three points.

First, that adrenalin must be used with caution in the presence of a weak pulse due to cardiac failure.

Second, that if digitalis is to be given for cardiac emergencies, it must be given intravenously and in much larger doses than we are accustomed to use, or we will not obtain the full benefit that digitalis is able to give until the time of the emergency is past.

Third, I hope that you will not use these doses intravenously unless you are certain that your patient has not been taking digitalis within the two weeks preceding.

objective signs of various disturbances of the pelvic organs of a pathologic nature are reasonably well known and easy of recognition, but the signs of disturbances in these organs of a purely functional nature are much less well known and are consequently much less frequently recognized as such. It is important, therefore, to scrutinize these cases most carefully to determine the signs of deranged function so that the knowledge thereby gained may be helpful in the recognition of altered function in other patients.

In these 105 cases there were, practically speaking, only three types of functional disturbance of any importance, and I shall now take up each in turn and give the various signs by which it may be recognized. Each of these three comprised about one-third of the total. I shall call them, respectively, hyposecretion, hypersecretion and ovarian dysfunction.

By hyposecretion I mean a condition of underactivity of the cervical and uterine glands. It is most common in under-development of the uterus, especially where there is any degree of ante flexion and the cervix is small and infantile. We have previously spoken of this condition as due to mechanically poor drainage, but it seems more reasonable to consider it merely a part of the general failure of development. As I have intimated, the cervix is usually small and conical, and the os is small, sometimes literally pinhole. The fundus may be quite small or nearly normal, but there is always present the sharp ante flexion of cervix on body which is the distinctive sign of lack of normal development. The secretion obtained from within the os in a typical case is thick and jelly-like. It is so poor a medium for the passage of spermatozoa that they soon become entangled and killed in it. This condition of hyposecretion is very common in cases of lowered fertility, being found in one-third of the cases analyzed.

The second group of functional disorders, hypersecretion, is what we have formerly called chronic congestion. In these cases the cervix is distinctly reddened, and running from the os can be seen an excessive amount of secretion. In early cases this secretion may be quite normal in appearance, like white of egg, but as time goes on it obviously becomes more irritating, and erosions about the os become common. Sometimes Nabothian cysts form in the cervix and greatly enlarge it, often infection supervenes, and we see typical pictures of endocervicitis or endometritis. The fundus of the uterus is usually larger and softer than normal, and it is easy to feel the engorged blood vessels beating. You will see that the end results in cases of this kind vary greatly. What I wish to emphasize is that primarily hypersecretion is caused by congestion

and that the finding of this condition is an indication of a functional disorder. It arises chiefly from over frequent and incomplete sex stimulation and is common in early married life. If infection does not take place it is often self-limited, with a return to full fertility when the primary cause has been removed.

Very little is known accurately about the third group—comprising cases of ovarian dysfunction. Objectively, these cases may present very little of importance. Some of them show hyperacidity of the vaginal secretion—a condition probably unimportant in itself, but merely indicative of deranged function elsewhere. Since in many of these cases ovulation fails to occur and the follicles are retained, it is not infrequent to be able to feel definite enlargements of the ovaries. Similar enlargement may be caused by the presence of blood (endometrial) cysts or of retained corpora lutea. They are all indicative of improper function, and if found require operative interference to correct them and permit the function to be restored to normal. These conditions, however—retention cysts, blood cysts, retained corpora lutea, etc.—are not to be considered as causing the failure of function (ovulation). There is some more general cause which produces these changes. As yet, we are ignorant of what it is, though there is some evidence that it acts on the ovary through the sympathetic nervous system. One might, therefore, hazard a guess that it is to be found in the hyperemotionalism not infrequently exhibited by these women.

This paper has had to deal with a subject which is still little understood. For that reason it is impossible to draw clean cut conclusions, but there are certain points which seem to me so thoroughly established as to warrant emphasis. In the first place, fertility is a variable quality. The degree of fertility is indicative of the completeness and normality with which the reproductive organs are functioning. It is intimately bound up with conditions of general health and with certain phases of the physiology of the reproductive organs. Several abnormal conditions of the body as a whole—namely, anomalies of nutrition, anemia, postural defects, foci of infection and endocrine disturbances—are found frequently associated with lowered fertility. Furthermore, these cases of lowered fertility all show some evidence of alteration of function. I have described the three forms of alteration which are most commonly found, namely, hyposecretion, hypersecretion and ovarian dysfunction. Finally, let me point out again the complexity of the problems involved and urge the need for the most careful study of them before there can be any hope of a final solution.

velops from interference with the normal support of the uterus and other organs, and the consequent appearance of chronic passive congestion.

This completes our theoretic discussion of what we should expect to find as causes for lowered fertility in the woman from our knowledge of her anatomy and physiology. What actually do we find? To determine this I have analyzed the records of some 250 recent cases. From this total I have excluded all cases of male sterility and all cases where the cause of sterility was some gross pathologic lesion—such as retroversion, closed tubes, large fibroids, etc. This procedure has left 105 cases in which a diagnosis of lowered fertility could fairly be made. It will be understood that in all the cases under consideration the marriage had been childless. In some of them there was a complicating lowering of fertility of the male as well, but in all the 105 there was definite lowering of fertility of the woman. What stigmata of altered health did they present? Thirty-eight were apparently normal, but 67, or more than 63%, showed definite evidence of something wrong from the general examination alone. These 67 cases could be classified under five headings—namely, those where there were (1) marked variations from the normal nutrition, (2) definite secondary anemia, (3) serious postural defects—particularly those associated with ptosis, (4) infected tonsils, and (5) endocrine disturbances.

Let us consider these five groups in order. Of these 67 cases, 22, or practically one third, showed marked alterations in nutrition. In 5 of these cases there was marked overweight, and they should perhaps have been grouped with the 6 cases of endocrine disturbances. This has not been done because it was difficult to prove endocrine trouble and because, in several, dietary changes alone were sufficient to correct the trouble and raise the fertility to normal. It goes without saying, however, that in such cases the basal metabolism should be determined, and the sugar tolerance, etc., tested to rule out thyroid or pituitary involvement. These women often show also a secondary anemia, and it is not until this, too, is corrected that it is possible to relieve the sterility.

The remaining 17 cases of the nutritional group present by far the most common and important problem. The women were all much under the average weight, even after making every allowance for heredity. They were often anemic as well and many showed signs of ptosis and bad posture. In some there was intestinal retention. This group, it seems to me, is plainly one due to failure of normal development. It can largely be eliminated by proper care of children, particularly during adolescence. It is interesting that many of these patients showed partial failures in the growth of the pelvic organs

as well. If this class of patient is taken early enough, the trouble can usually be entirely corrected, but if they have been neglected operative interference is often necessary.

The second group is also a large one, composed as it is of 17—slightly more than one-fourth of the total. These patients all showed a definite secondary anemia. The hemoglobin was less than 80 % in all—occasionally a little less than 70 %. These slight anemias may not seem to be of great importance, but I can only call your attention to the fact that many pregnancies follow their correction and that subjectively the difference of only 10 % in the hemoglobin may make all the difference between being half well and in full health. In this connection it is important to remember the monthly loss of blood to which the woman is constantly subjected.

Our third group consists of 14 cases with postural defects. It also is an important one, embracing more than one-fifth of the total. Practically all these women were, in addition, suffering from ptosis. These two allied conditions usually result from bad habits and poor development in adolescence. The mechanism by which they cause a lowering in fertility seems to be through their general lowering of constitutional vigor and through the tendency of the weight of the intestines pressing upon the pelvic organs to cause congestion in the latter.

The fourth group is made up of 8 cases, all of which showed chronic infection of the tonsils. It is possible that the action of infected tonsils in lowering fertility is entirely a secondary one, through the anemia which is so frequent an accompaniment. It is certain, however, that a very appreciable number of pregnancies follow the removal of infected tonsils where nothing else is done. It is hardly necessary to add that other foci of infection may be of equal importance.

The last group contains 6 cases where the evidence of endocrine disturbance—at least as a contributing factor in the lowering of fertility—seemed fairly strong. Most of these were apparently of thyroid—one or two of pituitary—origin. They usually were associated with menstrual disturbances, and the suggestion is strong from this fact, and from the finding of actual changes in the ovaries, that there may be some definite relationship between the two conditions. At this time, our knowledge is so far from complete that it is hardly wise to generalize as to either etiology or treatment from so few cases.

We have seen that in 67 out of 105 patients with lowered fertility some definite abnormality was found on *general* examination. All of the 105 patients showed alterations, chiefly of a functional nature, on *local* examination also. You will remember that this group had been selected from 250 by eliminating all cases with obvious pathologic lesions. Now it so happens that the

objective signs of various disturbances of the pelvic organs of a pathologic nature are reasonably well known and easy of recognition, but the signs of disturbances in these organs of a purely functional nature are much less well known and are consequently much less frequently recognized as such. It is important, therefore, to scrutinize these cases most carefully to determine the signs of deranged function so that the knowledge thereby gained may be helpful in the recognition of altered function in other patients.

In these 105 cases there were, practically speaking, only three types of functional disturbance of any importance, and I shall now take up each in turn and give the various signs by which it may be recognized. Each of these three comprised about one-third of the total. I shall call them, respectively, hyposecretion, hypersecretion and ovarian dysfunction.

By hyposecretion I mean a condition of under-activity of the cervical and uterine glands. It is most common in under-development of the uterus, especially where there is any degree of antelexion and the cervix is small and infantile. We have previously spoken of this condition as due to mechanically poor drainage, but it seems more reasonable to consider it merely a part of the general failure of development. As I have intimated, the cervix is usually small and conical, and the os is small, sometimes literally pinhole. The fundus may be quite small or nearly normal, but there is always present the sharp antelexion of cervix on body which is the distinctive sign of lack of normal development. The secretion obtained from within the os in a typical case is thick and jelly-like. It is so poor a medium for the passage of spermatozoa that they soon become entangled and killed in it. This condition of hyposecretion is very common in cases of lowered fertility, being found in one-third of the cases analyzed.

The second group of functional disorders, hypersecretion, is what we have formerly called chronic congestion. In these cases the cervix is distinctly reddened, and running from the os can be seen an excessive amount of secretion. In early cases this secretion may be quite normal in appearance, like white of egg, but as time goes on it obviously becomes more irritating, and erosions about the os become common. Sometimes Nabothian cysts form in the cervix and greatly enlarge it, often infection supervenes, and we see typical pictures of endocervicitis or endometritis. The fundus of the uterus is usually larger and softer than normal, and it is easy to feel the engorged blood vessels beating. You will see that the end results in cases of this kind vary greatly. What I wish to emphasize is that primarily hypersecretion is caused by congestion

and that the finding of this condition is an indication of a functional disorder. It arises chiefly from over frequent and incomplete sex stimulation and is common in early married life. If infection does not take place it is often self-limited, with a return to full fertility when the primary cause has been removed.

Very little is known accurately about the third group—comprising cases of ovarian dysfunction. Objectively, these cases may present very little of importance. Some of them show hyperacidity of the vaginal secretion—a condition probably unimportant in itself, but merely indicative of deranged function elsewhere. Since in many of these cases ovulation fails to occur and the follicles are retained, it is not infrequent to be able to feel definite enlargements of the ovaries. Similar enlargement may be caused by the presence of blood (endometrial) cysts or of retained corpora lutea. They are all indicative of improper function, and if found require operative interference to correct them and permit the function to be restored to normal. These conditions, however—retention cysts, blood cysts, retained corpora lutea, etc.—are not to be considered as causing the failure of function (ovulation). There is some more general cause which produces these changes. As yet, we are ignorant of what it is, though there is some evidence that it acts on the ovary through the sympathetic nervous system. One might, therefore, hazard a guess that it is to be found in the hyperemotion-alism not infrequently exhibited by these women.

This paper has had to deal with a subject which is still little understood. For that reason it is impossible to draw clean cut conclusions, but there are certain points which seem to me so thoroughly established as to warrant emphasis. In the first place, fertility is a variable quality. The degree of fertility is indicative of the completeness and normality with which the reproductive organs are functioning. It is intimately bound up with conditions of general health and with certain phases of the physiology of the reproductive organs. Several abnormal conditions of the body as a whole—namely, anomalies of nutrition, anemia, postural defects, foci of infection and endocrine disturbances—are found frequently associated with lowered fertility. Furthermore, these cases of lowered fertility all show some evidence of alteration of function. I have described the three forms of alteration which are most commonly found, namely, hyposecretion, hypersecretion and ovarian dysfunction. Finally, let me point out again the complexity of the problems involved and urge the need for the most careful study of them before there can be any hope of a final solution.

18 DIABETES DUE TO DISEASES IN THE LIVER?

By L WINFIELD KOHN, M.D

NEW YORK CITY

DURING the past three years, three patients after thorough study of the clinical history, physical examination, gastric and duodeno-biliary investigation and X-ray observation indicated that they had bile tract disease. It was after an interval of a year or more that diabetes developed. These patients evidenced considerable improvement of both the alimentary disorder and diabetes following surgery in one case and duodeno-biliary drainage in the other two.

The purpose of the report is to stimulate the profession to regard with favor the view, that many cases of diabetes owe their origin to disease in the liver, which itself, may be primary or secondary in nature. At the same time, I wish to state that I am not unaware that the pancreas seems to play a very important part in diabetic states, and that it is my belief that the liver is more concerned in primarily inducing diabetes than is the pancreas. This is not an entirely new point of view. Others have in the past suggested disturbances in the liver, muscle, kidneys, nervous system and endocrine glands as a cause of glycosuria, but the importance of the part enacted by the liver in the creation of the diabetic state has, in my opinion, not been sufficiently stressed.

CLINICO-PATHOLOGICAL CONSIDERATIONS

Much medical literature has in the past aimed to associate diabetes with pancreatitis and pancreatitis with diseases in other organs, particularly the gall bladder and biliary ducts. It seems that we have so definitely fixed our views regarding the relationship of pancreatic disease to diabetes that it is not improbable that the important bearing of disease or disturbances in other organs, particularly the liver, is overlooked. Lancereaux, Opie, Robson, Kehr, Mayo, Lichty, Barron and others have all stressed the association of bile tract disease with pancreatitis and that of pancreatitis with diabetes. More recently Peterman and Graham, Barber Bancroft and Heyd have emphasized the association of hepatitis with diseases in the biliary tract and only lately Heyd has demonstrated this liver change in many cases of chronic appendicitis. May we not move a step forward and look to the liver in which so much response and reactivity with respect to any stimulus throughout the body takes place as the organ responsible for the creation of the diabetic state? It might be well, rather than immediately to associate gall bladder or gall tract disease with pancreatitis, to consider the question of liver changes, then

later look to the pancreas for the part it plays in diabetes.

We may now feel certain that the liver is usually affected in diseases of the bile tract. It would seem that the question of the duration of the bile tract disease might have some influence in producing the disorder in the liver, as one might infer from the points stressed by Alvarez in his reference to the occurrence of biliary disease in childhood. He believes that biliary disease in adults often has its beginning in childhood, but does not manifest itself until later life. The factor of infection of the liver either thru the blood stream or lymphatics from the bile tract, or from some other focus as a source of infection, has been considered for a long time, as has the question of disturbances in metabolism. Interferences in the secretion of bile by the liver cells or in its excretion thru the ducts may also account for the creation of hepatitis, thru influences either chemical, i.e., retention of the bile acids and pigment, or mechanical, i.e. static pressure. In consequence of hepatitis, not only is there the likelihood of the destruction of the parenchyme, but it is also very probable that in many instances the liver cells lose their power of holding accumulated glycogen and this may very readily become a factor in the production of diabetes.

The predominating opinion at the present time regarding diabetes, is that it is due to a pathologic involvement of the islets of Langerhans in the pancreas. It is believed, that as a result, there occurs a deficiency in the internal secretion, to which is attributed the inability of the organism to utilize sugar. There is still some speculation as to whether the pancreatic disturbance is organic or functional in character. The exact pathology is indefinite, for despite the fact that many cases of diabetes have not shown a true anatomical change in the pancreas, the individuals had, from all other indications, a true diabetes. On the other hand, many cases with well marked pathology in the pancreas at autopsy, evidenced no diabetes during life. Falta does not look to pancreatic disturbance alone as the cause of diabetes, but regards it rather as a disease of the whole apparatus regulating sugar metabolism, which includes the nervous centers in the medulla and brain stem, connecting paths, pancreas and chromaffin tissue. Langdon Brown regards diabetes as a sign of exaggerated metabolism, evoked thru the sympathetic and associated endocrine glands, in relation to food material, etc. Allen contends that "no proof of direct participation of any other organ in the

etiology has been determined' and looks forcibly to the pancreas for the cause of this disease

PHYSIOLOGICAL CONSIDERATIONS

Regardless of the exact nature of the cause of diabetes, one outstanding characteristic is the defection of the organism in the utilization of carbohydrate. Carbohydrate as we know, is ordinarily stored in the body as glycogen and serves the demands made upon the organism for the production of energy. As the need asserts itself, the glycogen releases itself from its storehouse, and thru oxidation meets the demands of the metabolism.

The liver and the large muscles of the body seem to be the chief points for the storage of glycogen. The muscles because of their frequent use and consequent oxidation in their cells probably require the localization of glycogen in them, so that they may without hindrance meet demands. It is also quite possible that the glycogen stored in these muscles may have originally resided in the liver, from whence it had been transported in altered form to the muscles to fill the depleted supply. The liver is most likely the main storehouse for glycogen to which the general oxidative processes of the body look for fuel supply.

Most physiologists of today regard the non-combustion of sugar as the cause of hyperglycemia in true diabetes, and the reduction of the sugar holding capacity of the tissues of the liver as the cause of the hyperglycemia in pseudo-diabetes, such as, Bernard's pique, alimentary glycemia and phlorhizin diabetes. It is very possible that both these factors play a part in true diabetes and we can, at least theoretically satisfy our minds that the liver disorder may in a great measure be associated with such changes. Disease of the liver cells, one can readily understand, may disturb the glycogen storage capacity of each cell and one can also appreciate now glycogenase, a diastatic ferment found in the liver, blood and lymph, may be influenced by disease of the liver itself.

Araki found lactic acid and glucose in the urine of animals, the oxygen carrying capacity of whose blood had been diminished thru the respiration of CO, (asphyxia). In this case might we not have found the CO lesion in the liver, and this finding the result of its effect on the liver substance. Macleod found that if the liver were excluded from the circulation by means of an Eck fistula in the dog, no hyperglycemia followed asphyxiation. From this Macleod concluded that the acid carried in the asphyxial blood produced glycogenolysis in the liver cells. These two experiments certainly seem to point to the liver as an important factor in the production of hyperglycemia. Elias found that the intravenous injections of acids into dogs

produced a discharge of glycogen by the liver and a resulting hyperglycemia. Lusk found that the ingestion of 75 gms of glucose by a phlorhizinized dog in no way affects the respiratory quotient, which indicates that the animal has lost the power of oxidizing glucose, but the states that this loss in oxidative power does not in all probability occur on the first day of the administration of phlorhizin and may be due to acidosis.

Verzar has reported that the dog does not completely lose its power to oxidize glucose until the fourth day after pancreatectomy. This also is probably due to the increased acidosis. Lusk states that traces of acid prevent the oxidation of glucose and it is believed that this factor makes the glucose molecule invulnerable and non-destructible in diabetes. Murlin has obtained results, which indicate that if a depancreatized dog be given alkali he is able to oxidize some glucose. This seems to support the assumption that acidosis is strongly concerned in diabetes production. From the foregoing, it would seem that it is not quite proper for us to regard diabetes as a disease mainly of the pancreas. To look upon the liver and the blood, a fluid which is such great quantity and so intimately is concerned with it in physiologic function, as the more important tissues in which disorder has arisen might eventually reward us in our search for the cause and cure of diabetes. There is no doubt that the pancreas plays an important role in carbohydrate metabolism, but it is not necessarily the chief role. The pancreatic disturbances may be secondary and have developed only after manifest primary disease has occurred in the liver or the blood. The same may be said of the influence brought to bear by the thyroid gland and chromaffin tissues, or disturbances in certain portions of the nervous system proper, as in the corpus striatum of the brain or in some portion of the vegetative nervous system. The fact that the liver is the great detoxicating organ of the body, that it is concerned in practically every reaction that metabolically takes place in the human being, that it has such an important part in glycolysis and sugar storage, makes me feel that more attention should be given to its consideration as a factor in the production of diabetes.

DISCUSSION

Why is it, that in a phlorhizinized animal the oxidative power in all probability is not lost, as stated by Lusk, until after the first day? Why is it lost on the second day or thereafter? Is this oxidative ability lost because of the development of acidosis or is it due to the fact that the power of oxidation lies inherent in the liver or within some portion of the vast circulatory system within the liver and that as soon as the gly-

cogen supply has left the liver in large quantity, the opportunity for oxidation is lessened? In other words has the concentration of the glycogen in the liver been so reduced, that the furnaces within this organ or its vascular spaces have been deprived of their fuel to the extent that the fire has abated? Is not the liver the station where the potential factor for the ignition of oxidation resides? In these phlorhizinized animals the pancreatic islets have evidently not been destroyed, and the pancreatic hormone has in all probability not been decidedly removed. For the same reason as suggested above for the existence of hyperglycemia after giving glucose to the phlorhizinized dog, we might attribute the condition known as starvation diabetes. It was Hotmeister who discovered that the fasting organism is more susceptible to alimentary glycosuria than is the well-fed organism. If the pancreatic hormone controls the power of oxidation, why should the experiment of Raulston and Woodyatt, in which an intravenous transfusion of blood from a normal man into a diabetic individual aggravated all symptoms in the latter, rather than increased the sugar tolerance, as one would expect from the presence of the pancreatic hormone in the blood. The aggravation of the symptoms might have been due to some factor other than those intimately concerned in sugar metabolism.

In Verzar's experiment, why is it that the dog does not completely lose its power to oxidize glucose until the fourth day after pancreatectomy? Would this continuance of this oxidative power four days be attributed to the continuance of pancreatic hormone in the blood, or would it be due to the fact that acidosis had not yet adequately developed? Would it not seem more logical to regard the pancreatic islet secretion as merely the regulator of sugar metabolism, and that depending upon the disruption of the regulation, there will ensue a breakage in sugar storage function within the liver? Then in consequence of the break will follow an abatement of oxidation within the liver or the hepatic vascular areas. When we regard the diseased islets of the pancreas as the primary cause of diabetes, are we not confusing cause with effect? If we are to solve this puzzle, would it not be wiser and more fruitful to start the other way about, and look to the hepato-vascular system for the basic primary cause.

SUMMARY

1—Some special portions of the liver or of its vascular areas are probably affected and result in the production of diabetes. These special areas are probably concerned most intimately in glycogen storage function, as well as in the oxidative influence over sugar during metabolism.

2—It is not necessary to deny that the pancreas is concerned in carbohydrate metabolism.

It probably, to a degree and in a definite manner, aids in the regulation of this metabolism. The connection of the liver and pancreatic islets in carbohydrate metabolism is without doubt closely linked. Disturbance in one organ probably affects the other, but the disturbance does not necessarily have its origin in the islets. Should the disease first manifest itself in the pancreatic islets, which we assume are the regulators of sugar metabolism, then we might readily appreciate how secondary liver disease or dysfunction may rapidly arise. On the other hand, if the liver areas are first affected, we might also conceive how the regulating control of the pancreas would be lost.

3—It is not fair to assume that every diabetes is necessarily preceded or even associated with a pancreatitis.

4—It is exceedingly difficult to regard every hyperglycemia and glycosuria in their proper light and say that this case belongs to the group of true diabetes while another belongs to a group non-pancreatic in origin.

5—Because the pancreas is involved, it is hardly fair to assume that the disease had its origin in the pancreas. It is possible that the disease had its superinducing origin in some other focus in the body.

6—We must not ignore the fact that many diseases of the biliary tract and the liver are followed by glycemia or a lowered sugar tolerance. To say that these cases are not truly diabetic may also be an erroneous assumption, despite the fact that this form of the disease manifests itself for the time in a milder form than the condition which we recognize as true diabetes.

7—Diabetes may be a more complicated disease than many of us think, especially in its production.

8—The liver is concerned in the reaction of practically every disease of the organism. Certain workers have shown that it is affected in diseases involving the biliary tract, and recently it has been connected with the disease of the appendix. It would not be unfair to conclude that disease of any visceral organ may be associated with liver involvement. The influences of toxic states or poisons on the liver is well known.

9—Because the liver is involved in many diseases of the organism and does not in every instance result in the production of diabetes, does not imply that the liver is not concerned in the production of diabetes. It is probable that the liver does invite the development of diabetes only when it is affected in a certain determinate manner.

10—It is my present belief that the recognition of this particular manner of liver involvement holds the key to the cause and cure of diabetes.

A PSYCHONEUROSIS CASE REPORT

By WILLIAM B TERHUNE, M D, and AUSTEN F RIGGS, M D,

STOCKBRIDGE, MASSACHUSETTS

THIS is a case report of a patient afflicted with a psychoneurosis. Such a condition is not rare, the treatment is not unique, and the result obtained was to be expected. This report is submitted in order that certain methods of treating the psychoneuroses which are now being employed with a considerable degree of success may be placed before the medical profession in concrete form.

Case History—A man of twenty-nine years, unmarried, of sound antecedents, complained of having what he considered a very queer and incapacitating illness, one which he found difficult to describe. He stated that, having contracted a Neisserian infection a year ago, he had become apprehensive about his health. On Labor Day he happened to pass the office of a good genitourinary specialist and, having nothing else to do, thought it might be just as wise if he stopped in to ascertain what his condition was. The doctor gave him a thorough examination lasting some two hours and assured him that he was perfectly well, that there was no evidence of Neisserian infection, nor its sequelae.

The patient left the physician's office and a few minutes later, while walking down the street, he began to feel bad, felt rather faint, mouth dry, knees a little "wobbly," heart pounding, head "woozy," and he was also somewhat nauseated, but did not vomit. He was considerably frightened by these sensations, and on entering his office he found that he was pale, which frightened him still more. His friends in the office sent him into the hospital where he waited for several hours before the doctor came and told him he was all right, but did not attempt to explain his illness. He went home and every time he thought of this upset and wondered what it was, he would again feel rather badly, uncomfortable, and apprehensive. When he returned to his office the next day, expecting to be perfectly well, his uncomfortable feelings swept over him again and were so acute that he went home. He went to bed and while there with nothing to do, he noticed that he was holding his head in his hands and, remembering a friend who after losing his mind held his head in his hands, he began to wonder if he were losing his mind also. He tried to go back to work on numerous occasions, but the unpleasant sensations would always sweep over him, and he would have to quit. He came to New York on business after three weeks away from his job. There one of his friends, having recovered from a similar illness, described some of his own psychoneurotic symptoms, following which the patient had a tremendous recurrence of his

unpleasant sensations and fears, together with tachycardia, dryness of the mouth, increased perspiration, and a feeling of weakness. He was then seen by Dr. Frederick Tilney who referred him to us.

When this patient was first seen, he seemed rather a happy-go-lucky, energetic, intelligent individual, with a stable emotional make-up. He didn't make much of his illness. In fact, one had to draw him out in regard to what had happened to him. This was probably due to the fact that in the first place he was afraid that if he talked about it, his symptoms would recur, and secondly, he was rather ashamed of having such a condition.

The treatment consisted of getting him away from his old environment where such stimuli as aroused his conditioned psychic reflexes might be avoided until he had been trained to crystallize these responses into habits, and a sufficient length of time had passed to re-condition his reactions. Second, he was given a schedule which kept him busy all day on a budgeted regime of activities. Third, he was gone over very carefully from a physical standpoint and instead of telling him he was perfectly all right, a resume of his condition was given him, system by system, pointing out to him his complete physical and mental adequacy. A factor, of course, was the confidence he gradually acquired in the physician's judgment and a definite amount of friendship which arose on the basis of that confidence. This was, of course, an incidental occurrence rather than a therapeutic procedure.

As soon as the patient felt at home and was in a receptive mood, an effort was made to enlighten him in regard to psychoneurotic reactions in general, first explaining to him some of the principles of adaptation, the nature of the nervous system as the organ of adaptation, the part that the emotions play in one's life, mentioning the various physical concomitants of emotions and the discussion of the rather usual forms of mal-adjustment.

With this as a basis, he was led to more or less find for himself the cause of his difficulties. *First*, that he was a sensitive, intelligent, and emotionally stable individual and that such an illness as he had suffered was compatible with these characteristics, *second*, that following his Neisserian infection he had experienced a very real apprehension as to its consequences, plus shame that he should have had such an infection, plus disgust, *third*, with such an emotional background he went through a most intricate physical examination of serious moment to him during which his sympathetic nervous system was

already very sensitive to even small stimuli and was probably upset by the passing of sounds, massage of the prostate, and use of local anesthetics, *fourth*, that the physical sensations which seemed so queer and inexplicable to him were natural under the circumstances, that they were the physical concomitants of the emotions he had experienced plus other sympathetic phenomena resulting from the procedures and drugs employed in the examination, *fifth*, that the seriousness of his condition had been fixed in his mind by the solicitude of his friends, *sixth*, that reflexes formed by association with office and work at the time of his primary attack led to recurrences of his symptoms whenever he approached work, *seventh*, that naturally all of this seemed very queer to him, that, lacking information, he couldn't really understand it. Like all human beings, he had a dread of insanity, insanity likewise seemed queer to him and when he found himself feeling queer, it was only natural that his illness, by virtue of

its strangeness, should at once be associated with the queerest thing he knew of namely, insanity.

The patient was finally able to grin and say, "Well, Doctor, I guess I find the answer to all this. In the first place, I can understand that I am physically and mentally sound. In the second place, I can understand that having aroused these mechanisms in my body, they are not going to subside at once, it is up to me to accept them, smile at them, treat them in a more friendly fashion, and my experience already has been that if I so treat them, I can put my attention on other things which results usually in the symptoms quickly disappearing."

As a result of this explanation and attitude of the patient, he can no longer be described as having a psychoneurosis, that is to say, he no longer has an exaggerated response to what is in all probability a perfectly natural reaction. As a matter of fact, he is no longer having any more trouble either physically or mentally, and has been discharged as cured.

PRESENT DAY CONSIDERATIONS OF BRAIN TUMORS*

By GILBERT HORRAX, M.D.

BOSTON, MASS.

BRAIN tumors are of much more frequent occurrence than is commonly supposed.

They are always to be considered of surgical significance, first, because complete or partial removal is often possible, and second, because if removal is not feasible, palliative operative procedures are almost always necessary to preserve vision or to relieve the discomforts arising from increased intracranial pressure. The individual types of tumor may be considered in the order of their frequency, the figures given being based on the analysis of a thousand verified tumors from the clinic of Dr. Harvey Cushing. The surgical treatment will be taken up with each group.

1. *Gliomata*. These tumors arise from cells of the brain tissue proper and are the most frequent of all intracranial new growths, representing about 40% of the total. They occur at any age and in any part of the cerebrum, cerebellum, pons or midbrain. In general from a clinical standpoint, three main types can be recognized, namely, those which are partly or largely cystic, those which are more or less encapsulated, and those which infiltrate the surrounding tissue without a distinguishable border.

Gliomata are on the whole the most rapid in growth of all brain tumors, although this is not true of all types. They give rise to the usual pressure symptoms of headache, vomiting and

mental dullness, to which there is added in most instances the objective finding of choked disks. In some cases, however, there may be pressure symptoms, even advancing to coma, with normal fundi. Focal signs and symptoms depend upon the situation of the growth. Inasmuch as they are more often subcortical than on the surface, they do not tend to cause convulsions as frequently as do tumors of some other types. A small percentage of gliomata have areas of calcification within them and their situation can then be determined accurately by stereoscopic X-rays of the skull. When no calcification exists the X-ray shows merely the convolutional atrophy and increased vascularity due to intracranial pressure.

Treatment. If the situation of the tumor can be determined, the area in question should be explored either by an osteoplastic flap in case of the cerebrum or by a suboccipital procedure if cerebellar. An area of decompression should always be left. If the tumor is large and infiltrating it is probably best to leave it alone and subject the area to deep X-ray therapy. Some types of glioma respond extremely well to this treatment the patients being relieved of all symptoms sometimes for several years. If the growth is partially or rarely, wholly encapsulated an attempt at enucleation should be made. Even if all of the tumor cannot be extirpated, the patient can be given X-ray therapy with the probability of a length of time free from symp-

* Read before the Medical Society of the County of Oneida, at Utica May 19, 1925.

toms varying directly with the relative amount of growth removed. A wide margin can be given to tumors of this sort which occur in silent areas of the brain. When a glioma is found to be largely cystic, if not too deeply below the surface, as determined by the insertion of a blunt, hollow needle, a transcortical incision is made down to the cyst, its contents evacuated, and its lining fixed with Zenker's solution or 10% formalin. Sometimes a small nodule of glioma will be found protruding into the cyst, and this nodule often may be excised completely. This form of glioma is particularly favorable for surgical treatment, many patients being permanently cured, and other entirely relieved for five, ten or even twenty years.

In some instances no surface tumor will be disclosed nor will there be obtained any fluid by puncture. Presumptive evidence of a subcortical tumor in such cases is shown by flattening of the surface convolutions, or dislocation of certain structures, such as the Sylvian vessels from their normal position. If bleeding follows upon the withdrawal of an exploring hollow needle, this also tends to favor the presence of an underlying glioma, as normal brain tissue may be punctured in this way ordinarily without the slightest bleeding. These patients should be given the benefit of a decompression for the relief of headache and to preserve vision.

Gliomas of the pons and midbrain cannot be reached by any operative procedures. Patients with tumors in these situations should be given a decompression and subjected to deep X-ray therapy directed at the site of the lesion. Such measures often prolong useful life for a very considerable period.

2 Pituitary Tumors This group consists in two distinct types, the adenomas which represent 20%, and the suprasellar cysts, which constitute about 5% of all intracranial new growths.

The adenomas are strictly speaking, the only true pituitary tumors, and are really little more than an overgrowth or hyperplasia of the gland. They distend the pituitary capsule and thus cause gradual erosion and enlargement of the sella turcica. They may occur at almost any time of life, but are most frequent between the ages of 15 and 40. Pituitary adenomas should be considered as acting to this gland in a way similar to the way in which adenomas affect the thyroid. This manifests itself in waves of activity which are superseded by periods of quiescence, the gland or tumor of the gland becoming a little larger after each active period, but its normal secretion lessened. Such changes going on in the pituitary produce certain clinical pictures which we can recognize, the differences in secretory activity causing definite constitutional changes in the individual, and the increase in size of the gland exerting pressure upon im-

portant structures in its neighborhood. The clinical types are now fairly similar. Overactivity of the pituitary in adult life results in the skeletal changes which we call acromegaly, while hyperfunction before puberty cause true gigantism. If underactivity of the gland has come on before puberty, the picture is that of obesity associated with infantile genitalia, the "syndrome adiposo-genitalis" or Fröhlich's syndrome. After puberty there is often, but not always, some tendency to obesity, with feminine distribution of hairs in the male and amenorrhoea in the female. To all the above there is added usually some degree of drowsiness, an increased tolerance to carbohydrates, and a somewhat lowered basal metabolism. In addition to these forms, there are acromegalics, who although retaining the bony evidences of a previous glandular overactivity, have gone on to the stage of pituitary underfunction, and therefore show the corresponding constitutional changes just cited.

Important as are these constitutional changes, however, the principal, if not the only surgical manifestation of the pituitary adenomas, is due to the pressure they exert upon the optic nerves or chiasm. This pressure produces gradual loss of eyesight, which as a rule affects first the temporal halves of both fields of vision giving the typical bitemporal hemianopsia, although if the growth presses upon one optic tract just posterior to the chiasm, an homonymous hemianopsia will result. In the earlier stages these hemianopsias are not complete, but as the pressure increases, there is found every gradation from a slight notching of one or both upper quadrants going on to complete bitemporal loss, or even total blindness.

The diagnosis of a pituitary adenoma, as a rule, is not difficult. The patient seeks medical aid most often because of failing vision, and examination of the fundus oculi will reveal primary optic atrophy of greater or less degree in one or both eyes. The perimeter next shows a partial or complete hemianopsia, usually bitemporal, but sometimes homonymous in type, and X-rays of the skull will give evidence of at least some enlargement of the sella, which in most cases is outspoken. Finally the glandular manifestations may be numerous and typical, or they may be altogether absent, according to how greatly the actual pituitary secretion has been affected.

In regard to treatment, partial removal of the soft adenomatous struma from within the sella is the procedure of choice, and in the hands of surgeons familiar with intracranial conditions is not particularly hazardous. Deep X-ray therapy may be tried under careful supervision, but there are risks of sudden and dangerous upsets from this form of therapy.

The supra-sellar or pharyngeal-pouch cysts are seen most often in children below the age

of puberty, the most typical clinical picture being that of an undersized individual with some degree of adiposity and infantile genitalia. Any or all of the previously mentioned symptoms of pituitary underfunction may be present and in addition a certain percentage of cases in this group show a marked diabetes insipidus. Often these little people are, for their years, exceedingly advanced mentally, this feature being quite striking when present.

The diagnosis in typical cases is simple, as added to the above there is found usually optic atrophy and some form of hemianopsia, while in a large proportion of cases the X-ray will reveal a deformed or eroded sella. In many instances these cysts contain calcified material which shows in the plate as small opaque areas above the sella. On the other hand, these patients may show such marked signs of increased intracranial pressure, because of the large size of their cysts, that they may have choked disks instead of primary atrophy, and false localizing symptoms, particularly apt to be cerebellar in type, may lead to a faulty diagnosis or even an operation directed at the wrong site.

Treatment of the supra-sellar cysts is entirely surgical, the approach being by an osteoplastic flap over the frontal area with retraction of the frontal lobe to expose the region of the optic chiasm. In some instances the cysts can gradually be worked free of their attachments and completely extirpated, but the operative risks are considerably greater than in the adenoma group. In other cases the cystic fluid can be evacuated and the cyst wall partially excised. X-ray therapy has no effect upon cysts of this character.

3 *Meningiomas (endotheliomas)* These tumors represent about 12% of all intracranial growths in Dr. Cushing's series. They are the familiar, irregularly round, somewhat "potato-like," fairly firm, encapsulated tumors which have been described under various names such as endotheliomas, sarcomas, fibro-sarcomas, etc., owing to the fact that certain cell elements predominate in some, and different ones in others. They are all essentially similar, however, in that they arise from the meninges, are non-malignant, and are completely removable surgically. They do not in any sense invade the cerebral substance but as they grow, the brain is pushed away and depressed by them. Although their form is usually roughly spherical, they may assume almost any shape, some having an "hours-glass" appearance, while others are quite flat and not more than one or two centimeters in thickness.

The diagnosis of a cerebral meningioma may often be made with certainty, but at times none of their pathognomonic evidences are apparent. Unless they are situated in a "silent area" they give rise to the ordinary localizing signs char-

acteristics of the region involved. Owing to their slow growth these tumors should be suspected when the clinical history of intracranial disorder is of long duration—sometimes several years. Inasmuch as they always press upon the cortex at some point, they are apt to cause convulsions more often than the gliomas. Finally, in a large proportion of cases they cause characteristic bony changes in the skull adjacent to them and can be diagnosed easily by the X-ray. This change may take the form of an overgrowth of bone, or the tumor itself may invade the bone and even be present in the scalp.

In addition to these general considerations, meningiomas in certain situations present features which may be said to be almost characteristic. In the Rolandic area, usually growing from the superior longitudinal sinus, they produce true Jacksonian fits, the seizure in most instances starting with twitching of the opposite foot and having a typical "march" up the leg and then into the body, arm and often the face as well. Such seizures occur as a rule with no loss of consciousness, and with gradually increasing weakness of the side involved.

Another not infrequent location for meningiomas is on the floor of the anterior fossa, in the region of the olfactory groove, often on one side only, but sometimes growing across the median line. Such tumors present every characteristic clinical picture. In addition to general pressure symptoms, which may or may not obtain, there are signs of mental disturbance and deterioration. Finally, as localizing features, if the tumor is on one side only, there will be primary optic atrophy and anosmia on that side, and usually a choked disk and no disturbance of smell on the other. If the growth has become bilateral, there will be anosmia on both sides, while the eye-grounds may show choking of both disks, or a combination of choking superimposed on an earlier atrophy.

One more situation for meningiomas should be mentioned, namely, the post-orbital or anterior temporal region. Here the tumors are almost always of the flat type, but they cause great local bony thickening, and a characteristic unilateral exophthalmos.

The treatment of meningiomas is surgical removal if the localization can be accomplished. Occasionally the situation will be such that an approach is almost impossible, but the vast majority can be enucleated after a carefully planned osteoplastic resection. The skull in patients having meningiomas is always more vascular than normal, this feature being extreme in not a few, so that often a two-stage operation is either necessary or advisable. This great increase in vascularity of the bone is a further help in diagnosis as the deepened channels show well in the X-ray.

The prognosis for meningiomas is excellent,

patients making complete recoveries if no damage is done to the surrounding brain during their removal, provided that the pressure from their presence has not been so long continued that the optic nerves have become damaged or paralyzed occurred. Sometimes removal may be incomplete, the growth then recurring locally, but always benign. In patients who have had Jacksonian attacks before operation, these seizures may continue for a considerable time even after the tumor has been completely removed, but they are apt to grow less frequent.

4 *Neurinomas or acoustic tumors* form 90% of the total in this series. They are the typical cerebello-pontile angle tumors, present a chronology of clinical signs and symptoms which is almost unmistakable, and should be diagnosed more accurately perhaps than any other type of intracranial new growth. They are usually firm, encapsulated tumors, taking their origin from the sheath of the acoustic nerve, and microscopically resemble neurofibromas because of their large content of fibrous tissue. Sometimes they become softened and cystic.

In every case the clinical story begins with tinnitus on the affected side, followed or accompanied by a gradually increasing deafness on that side. These two symptoms may be followed immediately by the other manifestations about to be mentioned or they may occur years before and be entirely dissociated by the patient from his later symptoms. After a longer or shorter period, there occurs evidence of pressure upon other cranial nerves in the neighborhood, most frequently the fifth and the seventh, as shown by numbness, twitching or weakness of the face. If the growth extends downward toward the medulla the 9th, 10th, and 11th nerves may be irritated or pressed upon. Subsequent to the involvement of various cranial nerves the tumor begins to press inward constricting the aqueduct, and also to press upon the cerebellum. These circumstances give rise to general pressure symptoms from internal hydrocephalus as well as signs of cerebellar involvement, the latter most often noticed by the patient as staggering. Examination reveals objective evidence of the cranial nerve palsies, nystagmus, ataxia and other cerebellar features, while choked disks are usual, and certain if the the growth has produced backing up of fluid in the cerebral ventricles.

Acoustic tumors are approached by opening the skull widely over the cerebellum, incising the dura and retracting the cerebellar hemisphere on the side of the lesion. Occasionally the growth can be removed entirely but this, as a rule, is far too hazardous. Sometimes, too, the tumor is so vascular that only a few fragments of it can be taken away without grave risk of hemorrhage. In most cases the procedure of choice

is to split the capsule and then scoop out the mass from the inside, making the enucleation by this means as complete as circumstances allow. As these tumors are invariably slow growing, such an operation usually relieves pressure for many years, although there may still remain some degree of unsteadiness and difficulty in walking.

5 *Infectious granulomata (tuberculomas and gummas)* occur very infrequently in the brain in comparison to tumors, and represent only 4% of the cases in the series. They give the same type of pressure and localizing signs as do new growths, but may be suspected when there is an antecedent history of pulmonary tuberculosis or active syphilis as the case may be. Tuberculomas are not amenable to surgical treatment, the vast majority of patients with this type of lesion dying from tuberculous meningitis within one year after extirpation. Gummas of the brain should be removed if encountered at operation, but if merely suspected they will yield much better to antiluetic treatment if a preliminary decompression is performed. A decompression in fact may save vision while active treatment is being undertaken.

Under the heading "miscellaneous and metastatic" are grouped the remaining 10% of intracranial tumors. The metastatic are chiefly carcinomata and usually in women, sometimes occurring many years after a breast amputation. These patients often require a palliative decompression to relieve discomforts and preserve vision during the remaining life of the individual.

The miscellaneous tumors include such rare forms as the true cholesteatomata or pearly tumors, which are capable of complete removal, and other bizarre growths such as papillomata of the choroid plexus, angiomas and certain tumors which cannot be classified.

In conclusion two or three points should be re-emphasized. Brain tumors are by no means infrequent in occurrence, and their early recognition is just as important as the early recognition of any other serious malady. By this means patients may be saved from severe headaches and the discomforts of protracted vomiting, while in most instances the operative risk is lessened when the lesion has not advanced to the stage in which pressure symptoms are marked. Above all, in patients who have choked disks a brain tumor is by far the most frequent etiological factor and should be suspected at once rather than finally recognized after procrastinating with various forms of futile treatment in the vain hope that some less serious condition is at hand. Only in this way can valuable time be saved and the patient's vision preserved from serious damage or utter ruin.

THE VALUE OF BLOOD CHEMISTRY STUDIES TO THE SURGEON

By ARTHUR M. DICKINSON, M.D., F.A.C.S.,

ALBANY, N. Y.

WITHIN the last decade, the so-called laboratory side of medicine has developed at a marvelous pace and has brought to the aid of the physician much valuable information. The effect of this advance has been most noticeable in the field of medicine, perhaps less so in the surgical field, for the reason that medical men have kept more in touch with these advances. However the study of the chemistry of the blood in health and disease has added greatly to the diagnostic and therapeutic accomplishments of the surgeon. Indeed the modern surgeon owes a debt of gratitude to the patient laboratory investigators who have been responsible for these studies. These laboratory workers are slowly but surely making of medicine a more exact science.

In the past the question of surgical intervention was decided to a large extent by clinical judgment. The necessity for operation, the grading of the operative treatment, the selection of the safest time for operation, the choosing of the anesthetic and the pre and post-operative treatment were all based on this same factor. If the experience of the surgeon had been large and his memory had treasured up the lessons learned in the past, then his clinical judgment was good. On the other hand if opposite conditions prevailed then results were not so good. To appreciate these facts, one only has to recall the many ill-advised operations upon diabetics or nephritics or the high mortality rate of intestinal obstruction. Now the laboratory brings to our clinical judgment much valuable aid and conditions are markedly changed. Definite diagnoses are arrived at more early in the course of the disease, operations are graded to the strength of the patient, more intelligent treatment before and after operations is possible, all of which contribute to the safety of modern surgery. In other words these laboratory studies enable the surgeon to salvage from the scrap heap of disease many individuals who in years past were hopeless derelicts.

It might not be amiss to state at this time the so called normal values of blood chemistry studies in health.

Sugar	90-120 mg	Total N	P	N	25-30mg
Creatinin	1-2 mg	Chlorides			560-650mg
Uric acid	2-3 mg				
Urea N	15 mg	Plasma carbon dioxide			56-65

One of the major advantages which study of the blood chemistry brings to the surgeon, is reliable information with regard to renal function. In diseases of the kidneys we commonly

have nitrogen retention due to the impaired excretory function. The amount of retention is an indication of the degree of impairment of renal function. Furthermore it is an index of the decreasing reserve of renal function which must be properly evaluated before extra work is thrown upon the already diseased organs. Various methods of determining kidney function have been worked out. The quantitative analysis of a 24 hour specimen of the urine yielded valuable information. Renal function tests such as the phenol test checked the excretory activity of the kidneys. The Mosenthal test gives still further information. However blood examinations yield information which far surpasses in accuracy and value that which can be obtained by any of these methods. Studies of the nitrogen retention of the blood enable the surgeon to judge the risk of operation, to estimate the reserve function of the kidneys, to limit the operation to the strength of the patient, to choose the best time for operation, to direct intelligent treatment and select the safest anesthetic. An outstanding example of the use and value of careful blood chemistry studies is found in the case with prostatic enlargement. How carefully the surgeon works out the risk in this particular field is well known. He insists upon pre-operative treatment based upon blood studies, he operates when he has evidence of satisfactory elimination of nitrogenous excretions of the kidneys, the extent of operation is limited to the safe side by these same blood chemistry studies and post-operative treatment or secondary operation is likewise guided by it.

In the diabetic case blood chemistry studies are of paramount importance. Primarily we are enabled to affirm or reject the diagnosis of diabetes. This in itself means much. Until the advent of blood sugar determinations, the diagnosis of diabetes mellitus was based upon urinary examination and treatment had to be guided by the same procedure. We know that glycosuria does not always mean diabetes, for there are certain individuals who have a low renal threshold which account for the glycosuria. On the other hand there are diabetics who do not present glycosuria because of a high renal threshold which may be due to nephritis or arterio-sclerosis. John of Cleveland has shown that if we depend solely upon urinary examinations to affirm or reject the diagnosis of diabetes we shall err in about 31 per cent of cases examined. If this difficulty of diagnosis of diabetes by urinary examination exists, certainly intelligent treatment must be under the guidance of blood studies. In the

treatment of diabetes we have that recently discovered and very valuable aid known as insulin, which has done so much to dissipate the clouds of despondency which have hitherto enveloped the field of diabetic surgery. Its administration can best be directed by repeated blood sugar examinations. As in renal disease, so in pancreatic disease, the operative risks can be more accurately estimated, the operation graded to the patient and the treatment more safely carried out by frequent blood studies. The onset of coma, which in the past came suddenly out of a clear sky to overwhelm the diabetic patient, can now be foretold by the estimation of the carbon dioxide of the blood and so the surgeon is able to administer prompt treatment to prevent its appearance.

It has also been observed that patients with a severe infection often have a lowered carbohydrate tolerance and vice versa, those with diabetes have lowered resistance to infection. Thus a vicious circle is established in which infection contributes to a lowered carbohydrate tolerance and hyperglycemia results in diminished resistance to infection. Some of these cases do not present with glycosuria, and can only be correctly diagnosed by blood sugar examinations. Naturally, recognition of the diabetic condition and combined treatment for this and the infection yields better results than simple treatment of the infection alone.

Ileus is another condition in which blood chemistry findings are of decided value to the surgeon. Ileus as we know may occur following operations or independently of them. It may be due to a paralysis of one or more segments of the intestine or to mechanical obstruction of the lumen of the intestine. The mortality rate of ileus is much too high, which to a large extent is the result of delays in diagnosis and treatment. In ileus the condition of alkalosis develops due to vomiting, lack of nourishment or toxemia. Irrespective of the cause of ileus, the blood findings are similar and very characteristic. They also point to the rational method of treatment. The plasma chlorides are greatly decreased while the blood nitrogen and carbon dioxide combining power are markedly increased. With the rise of the carbon dioxide combining power above 100, tetany may be anticipated. Recognition of these conditions may be met by treatment under the guidance of blood studies. The administration of salt solution by rectum is a great aid in treating these cases with or without enterostomy. In the more critical cases glucose and saline given intravenously act with

greater promptness. In the border line case, the decision to operate can often be made by carefully watching the fall of the blood chlorides and the rise of the NPN. Furthermore the outcome of a given case can be prognosticated by these same studies.

Shock is another condition in which blood chemistry findings are valuable. Generally speaking the physico-chemical background of shock is the same regardless of the cause. Whether we subscribe to the theory of nerve cell exhaustion or that of splanchnic vasodilation or toxemia makes little difference. The end result is essentially a condition of acidosis. The outstanding change in the blood is a decrease in the alkali reserve or buffer substances with resultant decrease in the carbon dioxide combining power of the blood plasma.

We have learned that disease of the liver commonly coexists with disease of the gall bladder, and that the results of operations upon the latter depend to a large degree upon the extent of disease of the former. So in surgery of the biliary tract, estimation of the impairment of hepatic function is very important. It is true that the reserve of the liver is very great, but proper estimation of this reserve is of signal importance if major surgery in the biliary system is contemplated. The recently developed liver function tests utilizing phenyl-tetrachlorophthalein, rose bengal, etc., depend upon the ability of the liver to eliminate the drug from the blood stream. Where liver function is disturbed due to disease or injury the withdrawal of the drug from the blood stream is markedly delayed. The determination of the bilirubin content of the blood also affords us considerable information. Normally, this varies from 1 to 2 mg per 100 cc. In jaundice it may rise to 30 mg. An increase in blood bilirubin occurs before the slightest icteroid tinge of the tissues can be found and thus enables us to determine the presence of the so-called latent jaundice. By this test it is possible also to differentiate between obstructive and non-obstructive jaundice. So the determination of the bilirubin content of the blood is often the key to unlock the door of an obscure diagnosis in disease of the upper abdomen.

This paper is a rather brief review of the subject, but serves to point out the value of blood chemistry studies to the surgeon. Theoretical considerations have not been indulged in but the attempt has been made to adhere to definitely proven facts which are of clinical value to the surgeon in his daily work.

treatment of diabetes we have that recently discovered and very valuable aid known as insulin, which has done so much to dissipate the clouds of despondency which have hitherto enveloped the field of diabetic surgery. Its administration can best be directed by repeated blood sugar examinations. As in renal disease, so in pancreatic disease, the operative risks can be more accurately estimated, the operation graded to the patient and the treatment more safely carried out by frequent blood studies. The onset of coma, which in the past came suddenly out of a clear sky to overwhelm the diabetic patient, can now be foretold by the estimation of the carbon dioxide of the blood and so the surgeon is able to administer a prompt treatment to prevent its appearance.

It has also been observed that as the great a severe infection often have, which the med-hydrate tolerance and viturify its ranks and diabetes have lowered.

Thus a vicious circle of the Muller bill fecton contributemen's Compensation Law is tolerance and councils of medical men to whom ished resistphases of disputed cases shall be cases do either than to laymen who have not only be edge and training to discern the wheat examina chaff in medical testimony. It is no diabetical to refer medical points to a lawyer this and points to a physician. Since Assembly-simple tier is a recognized authority on the

Ileus is's Compensation Law and consulted chemistmen of two committees of the Medical surgeon of the State of New York there is a ing operspect that the bill will pass, and if it may be re will be a minimum of disputes over ments oills for treating injured workmen

structor

mortalit

to a la

diagn modern attack on the stronghold of diph-
tior is like that upon an entrenched military
of ne. When modern soldiers charge an enemy,
caus no longer rush forward in a mass that
and dies all the available man power, but they
the by individuals and small groups of sol-
chlo who rush forward in successive waves
blo a cloud of force overwhelm the enemy
prie attack also requires the co-ordination of
any branches of arms and supplies, and the
reparation extends back to the factories and
transportation facilities at home.

The front line attacking forces in diphtheria is comprised of family doctors, but behind them the State Department of Health represents the central staff, and the lay organizations represent the Red Cross and other civilian organizations that inspire the morale of both the people and the front line fighters.

The diphtheria prevention campaign so far has consisted of attacks by a few bodies of regulars, repr and principally by officials of Depart-
lth. These have occupied sections

greater promptness. In the border line case, the decision to operate can often be made by carefully watching the fall of the blood chlorides and the rise of the NPN. Furthermore the outcome of a given case can be prognor or cated by these same studies. age of

Shock is another condition in wbt an eye chemistry findings are valuation of Rural speaking the physico-chemical of Health, and shock is the same rega expenses on account Whether we subscrig income taxes. It would cell exhaustio questions as these could safely tion on the discretion of administrative bodies. as investigators" on the one hand and judge- on the other demand a strict interpretation of the letter of the law, and so the legislators are almost compelled to fill the law books with more enactments than can be remembered or digested.

Physicians are also compelled to be on the defensive against many bills. There are chiropractor and naturopath bills whose objects are clearly evident. There are other bills drawn so cleverly that only an expert can discern their hidden import, but their disguises are plainly evident to those who have kept track of medical legislation for years.

The physicians of New York State are now in a position to handle medical legislation better than ever before. The committees on legislation in past years have made an excellent reputation for the physicians, and the legislators are outspoken in praise of those who are responsible for presenting the point of view of the physicians. It remains for the doctors of each district to impress their legislators with their own scientific outlook on public health problems.

THE TOXIN-ANTITOXIN CAMPAIGN

of the enemy's trenches in Auburn, Syracuse, New York City, and other strategic points where they have demonstrated the vulnerability of the enemy and the best plan of attack.

The family doctor is the individual soldier in the front line of attack and on him all preparations center. He must charge the enemy and deliver the final blow with his hypodermic armament.

The doctors in this campaign are not actuated by commands, but by the standards which have been set by the physicians in Departments of Health and by the leading pediatricians. County medical societies are endorsing and promoting the work, and lay public health organizations are preparing the people to co-operate with the health forces.

The Medical Society of the State of New York is actively represented on the general committee that is promoting the toxin-antitoxin campaign, and it urges its members to prepare themselves to give the immunizations to the young children of the families whom they treat.

DR GROVER W WENDE—AN APPRECIATION

Dr Grover W. Wendé, who was fatally injured by a trolley car in his home city, Buffalo, on February 9, was one of the leading dermatologists in the United States. He was Past President of the Erie County Medical Society and of the Medical Society of the State of New York, and during the war he was selected by the Surgeon General as a special advisor in venereal diseases.

He took an active interest in public health problems and his last official act was to preside at a meeting of the Central Nurses' Registry of Buffalo of which he was president.

In his private life, Dr Wendé was no less noble than in his official career. His rugged character and human traits of manliness were combined with a native kindness and warmth of heart which ever reflected the gleam in his eye and the suggested smile on his lips. He was the friend of his medical colleagues and often went out of his way to help a young practitioner. He was always ready to help others to achieve the high measure of usefulness that was his.

Resolution Passed by the Executive Committee

WHEREAS Doctor Grover W. Wendé rendered distinguished service as President of the Medical

Society of the State of New York, as Delegate to the American Medical Association, and in constant and devoted service to organized medicine for many years and

WHEREAS, He established a brilliant reputation for the highest attainments in Scientific Medicine, as practitioner and teacher in the field of Dermatology and

WHEREAS, His strength of character, breadth of vision, modesty, and charming personality endeared him to all who knew him, and

WHEREAS, The Executive Committee of the Medical Society of the State of New York feels that the Society has sustained an irreparable loss in his untimely death, therefore be it

Resolved, That the Executive Committee extend to the family of Dr Grover W. Wendé sincere and heartfelt sympathy, and that these resolutions be spread upon the minutes of the Executive Committee and published in the NEW YORK STATE JOURNAL OF MEDICINE

NERVOUSNESS

Cases of mental disorders in their incipency nearly always come under the care of family doctors. The afflicted person is sleepless or suffers with pains and other uncomfortable feelings, or is "nervous" and apprehensive without apparent cause. When a patient complains of something that is tangible—a pain in the side or "gas on the stomach"—the doctor can readily reassure him that what he has is nothing serious, and that he will not have a cancer or go crazy. But sometimes the condition about which complaint is made is only the cloak of the real difficulty—an excuse which conceals the real condition. These cases are undesirable to most doctors and physicians try to get rid of them on the ground that the trouble is imaginary.

Granting that the physical condition is imaginary, the fact remains that the mental state is abnormal and pathological and may lead to a disorder that is as disabling as a broken leg or pneumonia. It is the duty of family doctors to diagnose and treat mental disorders with the same care that they devote to physical conditions. The science of psychiatry is systematized, standardized, and simplified to such an extent that a family doctor can readily understand its principles. The family doctor is peculiarly well qualified to diagnose and treat incipient mental conditions, because he is informed regarding the home conditions and the family history of the patient.

A family physician has to give due consideration to the popular conceptions regarding mental disorders. The most common early manifestation of mental trouble is what is popularly called "nervousness." A "nervous" person is often popularly credited with an unusually strong brain, because he seems to have increased sensitiveness and keenness of imagination and a receptiveness to suggestions. People fail to realize that an excessive emotional response is an abnormal mental act which borders on the pathological. It is in reality a mental unbalance. But while persons generally are willing to be called "nervous," they resent the imputation that they are mentally "unbalanced."

It is one of the principles of the practice of psychiatry that the physician shall appear to give the patient credit for an excellent mentality. The unbalanced patient usually reasons correctly, but he starts from wrong premises. It is the object of the physician to discover the abnormal condition which underlies the patient's line of reasoning. Usually, the underlying condition is an unfounded fear. A child, for example, is severely reprimanded for a trifling sexual commission and is told that everybody is ashamed of him. As the sexual feeling naturally continues, a sense of shame and wrong doing may be balanced against a natural desire of the body in a life-long conflict which may find expression in the form of nervous states, and later in domestic quarrels. A kind

family physician who can discover the origin of this mental state can usually cure the mental condition readily

When the cause of a fear is explained, the mystery disappears, nervousness ceases, and the unpleasant condition may even inspire pleasure and confidence. The weird tremulo of a little screech owl at midnight is a potent cause of night terror for a small child. But when the cause is discovered and the explanation made that the noise is the happy song of a little bird

guarding the child, the sound becomes a song of welcome reassurance

The newer standards of the practice of psychiatry require the family doctor to study the unreasoning fears of his "nervous" cases and discover the conditions which give rise to the fears. These studies will have an effect beyond the immediate present, for they constitute the most hopeful method of the prevention of insanity.

A case illustrating some of the points of this editorial is described on page 185 of this issue

LOOKING BACKWARD TWENTY-FIVE YEARS

The February, 1901, issue of this JOURNAL contains two articles on diphtheria which illustrate the state of medical thought regarding diphtheria during the slow evolution of the modern conceptions regarding the disease. The first article is on two epidemics of diphtheria in Ithaca traced to milk supplies and was by Dr. Chauncey P. Biggs, brother of the late Commissioner of Health of New York State. The introduction discusses some previous epidemics that were presumably milk-borne and states that in one epidemic the cowyard received household sewage and that two members of the family had diphtheria. In explanation of the transmission of the disease in former epidemics, Dr. Biggs quotes

"It seems probable that the udders of the cows as they lay in the litter may have become infected and the bacilli may have fallen into the milk during the milking. Another possible factor in the contamination of the milk was a sick chicken found on the dairy yard. Clinically the fowl had diphtheria. False membrane most typical in appearance was found in its throat and its nostrils."

"Cultures were made from the milk, but failed to develop the characteristic Klebs-Loeffler organisms. The strong evidence of milk infection is the fact that a large percentage of the patients were supplied by certain milkmen, yet the way the milk became infected could not be explained. Very strong evidence of the infected character of milk was shown in one epidemic in which liberal users of boiled milk wholly escaped."

The article states that there was a supposed connection between chapped and ulcerated affections of the teats and udders and diphtheria, and that diphtheria of the teats is known in England as chapped teats. It quotes one authority as saying "It is difficult if not impossible to account for the infectious qualities of the milk in those epidemics where diphtheria could not be found at the milk farms or shops unless we are permitted to look to the cows themselves as a source of infection. It is further suggested that in many of these cases it is probable that we have to deal with a staphylococcus or streptococcus infection."

In describing the Ithaca epidemic the author says: "The first case had been treated in the be-

ginning and reported to the Board of Health by a physician who had lost his standing in the family by his effort to protect the neighborhood and observe the regulations of the Board of Health. He had been summarily dismissed. It is presumable that the family physician in the second case had visions of similar treatment and he decided not to report the case."

The report goes on to describe a series of cases with several deaths in the practice of this second doctor "who did not believe in antitoxin."

The second article is by Dr. Veranus A. Moore on the control of diphtheria in small cities and country districts from the bacteriological standpoint. Dr. Moore was then, as now, a leading professor in the State Veterinary College and an authority on the bacteriology of milk. His article is a discussion of the epidemic described by Dr. Biggs and a plea for the method of control which he calls the "Culture Method." He states that "while the method is enforced in large cities, it has not been generally adopted outside of the thickly populated cities."

What are now called carriers were called "Germ Cases," and Dr. Moore recognized their dangerous nature. However, he said, "In this state the Board of Health seems to hesitate to consider 'Germ Cases' to be sufficient danger to warrant the treating of them, so far as quarantine is concerned in the same category as clinical ones. This seems to be unfortunate for the enforcement of safe quarantine as defined bacteriologically will in some cases be impossible, unless the local authorities are sustained by the State Board in Ithaca. We had difficulty with one such case, and the defendant secured complete legal advice that quarantine could not be lawfully maintained if the throat showed, macroscopically no signs of disease, and this opinion was acquiesced in by the Commissioner of the State Board of Health. It is to be hoped that ere long the law will recognize the carrier of virulent diphtheria bacteria, no matter what the physical condition may be, as a fit subject for therapeutic or prophylactic treatment and isolation."

Dr. Moore closes his article with a column plea for the adoption of the culture method of diagnosis and control by all the communities of the state, rural as well as urban.

MEDICAL PROGRESS

The Recent Cancer Research in London—Nather, a Vienna surgeon, recently delivered an address before a local medical society which appears in the *Wiener klinische Wochenschrift*, December 10, 1925, with especial reference to cancer research. At the instigation of Professor Eiselsberg he had made a special trip to London to investigate the status of the subject at first hand. He visited the London Cancer Hospital and Imperial Cancer Research Institute. The former is no less an active experiment station than the latter. The writer mentions the routine use of the Fry serological test, which gives positive results in 70 to 80 per cent of all cases, and in his opinion it possesses no advantage over the Freund-Kaminer reaction. He mentions with approval the work of Kennaway of the chemical division of the Cancer Hospital, who specializes at present in the carcinogenic substances present in tar, paraffin, etc. This scientist has prepared a tar-like substance from human skin and subcutaneous tissue which can generate mouse cancer. Neither Gye nor Barnard is connected in any way with either of these cancer institutions for Gye does his bacteriological work in the Field laboratories at Mill Hill, near London, while Barnard pursues his optical studies in his private laboratory (formerly a hospital for consumptives) in Hampstead. The writer after a detailed description of the work of Gye and Barnard sums this up in stating that Gye has successfully cultivated the Rous virus but has not yet shown any true pathogenicity beyond the production of Rous's fowl sarcoma. Barnard's service has been in the direction of increased visibility and of demonstrating a new method of reproduction in the most minute microorganisms.

A Study of the Rous Chicken Sarcoma No. 1—T. J. Glover, M. J. Scott, Julian Loudon, and J. M. McCormack (*Canadian Lancet and Practitioner*, February, 1926, lvi, 2) have repeated the work of Rous, Gye and Barnard with Rous chicken sarcoma No. 1, to which they add some original investigations along similar lines. They claim to have isolated, cultured, and described a morphologically similar, Gram positive, pleomorphic organism from the fresh tissue of Rous chicken sarcoma No. 1, from human carcinoma, mouse carcinoma (63), rat carcinoma, human sarcoma, and rat sarcoma (Jensen), also from the blood of the hosts of these malignant growths. A salient feature of the morphology of the organism of Rous chicken sarcoma No. 1, which is also common to organisms isolated from other malignant growths, is that there is a fil-

terable phase, and in this filterable phase the organism is invisible with the highest power of the ordinary microscope. The authors believe that the filterable organism from Rous chicken sarcoma No. 1, reported by Gye, is the filterable phase of this pleomorphic organism. They have demonstrated that when the clear, transparent Buchner (or sand) filtrate from Rous chicken sarcoma No. 1 is treated with chloroform and heated, according to the technique which they describe, the organism is not killed, but is attenuated and will not produce growths in this state, when the organism, as cultivated from this chloroform-and-heat-treated filtrate, is placed in the culture medium and incubated under either aerobic or anaerobic conditions, a pure culture is obtained in from forty-eight to seventy-two hours which shows all the characteristics of the organism cultivated from the fresh tissue, and again produces true spindle-celled sarcomatous growths. The authors maintain that the etiological factor in sarcoma is the pleomorphic organism herein described, holding at the same time that infection does not take place clinically unless the resistance of the cell has been previously lowered.

Parallelism in the Treatment of Tuberculosis and Cardiac Disease—Horace John Hawk (*Archives of Internal Medicine*, January 15, 1926, xxvii, 1) relates his experience in the treatment of cardiac disease in a modern tuberculosis sanatorium. This quite novel experiment was carried out under the auspices of the Metropolitan Life Insurance Company in its Sanatorium at Mount McGregor, where for several years it has cared for patients with cardiac disease as they have been recognized among the company's staff of employees. A comparative study of the mortality rates of tuberculosis and cardiac disease shows that a cut of more than half in the tuberculosis mortality is in sharp contrast to the mortality from heart disease which has increased 31 per cent during approximately the same period. Some idea of the enormity of the problem presented by heart disease can be obtained when we consider that a conservative estimate indicates that 300,000 children in the United States are thus affected, and will carry this serious disability throughout their precarious lives. The personnel and equipment of the modern tuberculosis sanatorium are peculiarly well adapted to the treatment of heart disease. Separation of the cardiac patient from the environment in which he got sick is often quite as important from the standpoint of recovery as it has proved to be in the treatment of tu-

berculosis Specifically the cardiac patient requires rest in bed The general plan of treatment provides for complete bed rest of every patient until the essential laboratory examinations have been made In the sanatorium the period of bed rest averaged forty-four days The patient's physical resources are tested gradually to determine the limits within which he can exercise without danger This period of graduated exercise is continued persistently until it is demonstrated that the vascular system either has or has not enough resources to enable the patient to resume work, or until he can take up an occupation Of 412 cardiac patients discharged from the sanatorium up to Dec 31, 1924, 198, or 48 per cent, are able to do full time work, 13, or 3.2 per cent, can carry on modified work, 109, or 26.4 per cent, are unable to work, and 79, or 19 per cent, are dead Many tuberculosis sanatoriums could be adapted to the treatment of cardiac patients, and the number of heated rooms and wards could be increased without undue expense to care for the type of patients requiring a uniformly mild atmosphere, such as those with badly broken compensation and those having associated severe nephritis The Nauheim baths, which have been so extensively used in the treatment of some forms of cardiac disease, could be readily and inexpensively given in any institution

Chronic Nasal Diphtheria and Atrophic Rhinitis—The term diphtheria carrier may mean nothing more than that non-virulent bacilli are found in the throat or nose It is immaterial as a rule whether a carrier has or has not suffered from the disease himself During the World War it was noted by German army surgeons that in some small epidemics carriers outnumbered actual victims of the disease Experience differs greatly as to the duration of the sojourn of the bacilli in the host The maximum has been placed as low as 3 months but in certain conditions, such as atrophic rhinitis, this sojourn is believed to have extended to 2 or 3 years Abraham, writing on the relation of atrophic rhinitis to nasal diphtheria (*Deutsche medizinische Wochenschrift*, December 18, 1925), says that he has examined many patients with atrophic rhinitis for diphtheria bacilli and has found them in only thirteen The bacilli were the genuine Klebs-Loeffler organisms although nothing is said of their virulence In only two of the 13 was there a history of clinical diphtheria The rhinitis was in the early stage, or at least there were no long standing cases and no sinus complications The symptoms comprised purulent discharge, crusting headache loss of smell, and prostration Under the circumstances the author suggests the possibility that this entire series of cases might have been chronic nasal diphtheria Pfeiffer, with an experience similar

to the author's concluded that an initial nasal diphtheria may bring about an atrophic rhinitis If the author's cases were post-diphtheritic it is evident that the early stage of nasal diphtheria can pass unnoticed, for there was no evidence of membrane formation at any time There would evidently be a risk in operating on these patients before the nasal passages were sterilized The author treated his patients with antitoxin, an autovaccine from a stock culture, and local disinfectants

Diagnostic Significance of the Endothelial Symptom—This symptom which was originally known as the Rumpel-Leede phenomenon, was believed at first to be pathognomonic of scarlet fever It is dependent on a heightened permeability of the capillaries, as a result of which stasis due to constriction of the upper arm is followed by some degree of extravasation of blood varying from a few puncta to large confluent macules In an article in the *Munchener medizinische Wochenschrift* of December 25, 1925, Stephan says that the phenomenon, far from being specific, is practically universal, it cannot be induced save in the arm above the elbow, and cannot be elicited by dry cupping or any other kind of mechanical resource It has been studied exhaustively by the author and others and is now known commonly as "the endothelial symptom" It is well marked, relatively speaking, in three distinct classes of cases First, direct injury to the endothelium of the blood-vessels, such as arises in bacterial and chemical intoxications, and further in avitaminosis The second group has an endocrine component seen especially in Graves's disease and ovarian dysfunction, hence at time preceding menstruation The third group, which is mentioned without comment, comprises cases in which there is some disease of the central or peripheral nervous system In each of the three groups the phenomenon is present with sufficient frequency to be known as a positive endothelial symptom In order that the test may be uniform the author directs that the constriction be made by a broad rubber band applied on the upper arm half a hand's breadth above the bend of the elbow, the compression should be sufficient to make the arm feel heavy and the hand slightly numb although the radial pulse must remain perceptible The band must be left in position five minutes

Progress of Our Knowledge of Spasmophilia—According to Lesne and Turpin (*La Presse Médicale*, January 2, 1926), a distinction must be made between the basic spasmophilic state and the active manifestations (crises) of tetany The writers do not attempt to elucidate the nature of the former, which is an inherent overexcitability of the neuromuscular system,

but hold that the factor which elicits the manifestations of tetany is a blood state which has two components, one a disturbance of the acid-base equilibrium, the other representing a fall in the amount of the ionized blood calcium. Four theories have been active in the explanation of tetany, known respectively as the parathyroid, alkalosis, toxic, and calciprivic. Parathyroid tetany is apparently a special form, chiefly experimental, which is quite independent of the other, or clinical type. The toxic theory is based largely on the fact that animals deprived of the parathyroid glands have lost their natural resistance to poisons of various kinds and hence the significance of the theory is directed rather toward the parathyroid than to the ordinary tetany. There remains the alkalosis and the calciprivic theories which do not exclude each other and may be said to point to a common blood condition of recurrent or periodic character. A blood state somewhat similar to this has been encountered in epilepsy by Bigwood.

The Westphal Pupillary Phenomenon Following Epidemic Encephalitis—Westphal, the neurologist of Bonn, writes of the phenomenon which he was the first to describe over four years ago and which has now a large literature. Formerly spoken of as a catatonic rigidity of the pupil, it should now be known in the author's opinion rather as "alternating rigidity" or "mobile spasm" of the pupil. The earlier name was given because it was originally held that the pupillary condition agreed with that seen at times in catatonic dementia precox, which would seem to point to a process in the corpus striatum. The author gives numerous case histories in which the pupils are described. The first patient was not seen until nearly two years after his encephalitis first appeared. The pupils were of medium width and were seen to be rigid when light was thrown on them from a pocket flash. This condition stood in some necessary relation to spasm of the orbicularis, for the pupils were seen to be quite normal when the spasm was absent. In some of these cases it was necessary to force the eyes open in order to apply the pupillary test. The fact that the rigidity develops when the beam of light is thrown on the eye, when normally the pupils should contract, has also given the name "mydriatic rigidity" to the phenomenon. Several of the cases were in patients presenting the full post-encephalitic Parkinsonian syndrome. Some neurologists have found the symptom common, others rare, in these post-encephalitic cases—referring always to epidemic encephalitis because the phenomenon has not yet been seen after secondary focal encephalitis. There is an affective factor in some of these cases, for when the attention can be diverted sufficiently the phenomenon may be absent. The rationale of this pupillary behavior is still ob-

scure—*Deutsche medizinische Wochenschrift*, December 18, 1925.

Feer's Disease—This condition was first described as an autonomous affection by Feer in 1922, although it had been known as a syndrome before this period, at least in America and Australia. Feer was followed by Jaeger, and M. Muller, who is assistant to Professor Birk, the pediatricist of Tübingen, is the third to report a case. This occurred in a child of three years and was chronic in type, ending in recovery. The chief symptom is the recurrent sweating which causes secondary changes in the skin such as vesicle formation and desquamation, the extremities also being cyanotic. The skin is cold, damp and bluish-red. The next most striking symptom is motor weakness and tremor. The pulse is rapid as in Graves's disease and the blood pressure is increased. There is nocturnal restlessness with insomnia. In the author's patient there was spasmophilia to the induced tests although this symptom is not mentioned by Feer or Jaeger. The author makes no comment on a certain parallelism with hyperthyroidism and Graves's disease. The patient was submitted to the pharmacological tests. Adrenalin increased the blood pressure slightly and brought the pulse from 168 to 142. Pilocarpine made the pulse still more rapid than the disease itself—152 to 164. Atropine, given as a test, acted in a striking fashion, for the cold, moist, and livid skin became warm, dry, and bright red. This drug was then given therapeutically and the child made a brilliant recovery. Before the test the only remedy giving any relief to the patient had been large doses of bromide which calmed the restlessness and induced sleep.—*Muenchener medizinische Wochenschrift*, December 25, 1925.

Radiotherapy of Postoperative Pneumonia.—Fried returns to this subject after an increased experience, his first article having been based on a comparatively small material. It is known that pneumonia may follow abdominal operations in something like 5 to 10 per cent of all cases and that the mortality may be extremely high in individual experience even to the full 100 per cent. There has been no successful treatment unless the use of ethylhydrocupreine may be so called, so that the author felt justified in testing the x-ray. He is by no means alone in his employment of this resource for the affection in question, for in addition to his own experience he quotes the recent figures of others. One of his colleagues had nine recoveries in fifteen cases, another eight in ten cases, while Kutscher has collected notes of fifty-seven recoveries under this management, evidently not including the author's own material, which comprises forty cases with but one death, although seven others were not benefited by the treatment. In other words, the author cured 80 per cent of his patients and had a mortality

of but 25 per cent. Despite this apparent reversal of the usual percentages the author makes no extravagant claims as yet. The first question to suggest itself would have reference to the utility of this treatment in ordinary pneumonia. He has tested it in a few cases of both lobar and broncho-pneumonia with apparent success. In regard to the technique, this is described imperfectly, probably because it is undergoing constant change and no standard can be laid down. Nothing is said of the number and frequency of exposures. The focal distance is apparently from 25 to 50 cm., the filtration one-half inch each aluminum and zinc, the dose 80 to 120 erythema doses, etc. The rationale is quite unknown, the rule has been deference by crisis or steep lysis.—*Klinische Wochenschrift*, January 1, 1926

Paresis and Syphilitic Aortitis—The relationship between these manifestations of syphilis is by no means apparent, for while some authorities have grouped them both in an alleged quaternary stage of the disease, others call attention to the fact that syphilis of the aorta is certainly not a neurotropic manifestation and that vascular syphilis in general should be ranked under the usual manifestations of the disease, while metasyphilis is neurotropic. Coenen, pathologist of the University of Bonn, having read a recent communication of Kessler to the effect that mesoarteritis was present in 66 per cent of his autopsies on victims of locomotor ataxia, began a study of the records of his own clinic for paresis. Of 147 patients seen since 1919 about 43 per cent had aortitis while in the course of a long period before the late war the figure was but 22 per cent. This brought up the question of the increased incidence of aortitis and its possible cause. He consulted the records of other clinics and while in one series the current percentage was but 33 in another clinic it was 50. Hence there can be no doubt of an increase, although how large is uncertain. In addition to these autopsy figures clinicians like Finger and others have likewise noted an increase in the incidence of aortitis, without especial bearing on metasyphilis. This increase coincides roughly with the introduction of arsphenamine therapy and raises the perfunctory question of the possibility that this drug in some way may have been responsible for the increase. This does not seem a rational explanation, for usually metasyphilis is associated with insufficient early treatment of syphilis.—*Klinische Wochenschrift*, January 1, 1926

Medical or Surgical Treatment of Gastric Ulcer—The *Munchener medizinische Wochenschrift* for January 15, 1926, contains four articles on this subject which are inspired by a recent article of Professor Morawitz, an internist, in which he seemed to be favorably disposed toward

the surgical treatment of this affection. Lehmann, the first contributor, speaks of the surgical indications of ulcer which are not really the ulcer in itself but certain complications—perforations, stenosis, and hemorrhage, all given by the old writers, to which could be added others such as pylorospasm and chronic gastritis. It is these complications or sequelae which create indications for surgical intervention.

Schwarz mentions both spontaneous and post-operative hemorrhage as surgical indications and formulates these as follows: (1) Chronic recurrent hemorrhage is always a surgical affection, (2) Acute severe hemorrhage is never a surgical indication at first but becomes one after internal management has failed. Bleeding ulcer should be treated by (a) suture, (b) invagination, or (c) excision. It, in a case of perforation, operation is resorted to within the first six hours there should be practically no mortality, while failure to operate will mean a very high mortality.

König had already expressed himself at length in an article in the same journal of January 8. In this article he had noted that of the 462 cases referred to by Morawitz as having been treated medically, no less than 105 had been referred to the author finally for surgical treatment. Morawitz is a partisan of the spastic theory of the origin of this affection but this view König is unable to share, his belief being based upon a number of animal experiments. He says further that even if vagus irritation will cause ulcer it is hardly possible to cure ulcer by division of the vagus for the author has done this operation with little or no benefit to the lesion. Should the surgeon operate on the diagnosis of the internist? The writer in thus acting has of course often found ulcer, but sometimes has found only the condition described as "gastric ulcer without ulcer." This may mean adhesions, division of which will cure the basic condition for the time being although such cases may relapse, and then he has sometimes actually found ulcer at the second operation. Or "ulcer disease without ulcer" may mean chronic gastritis. Morawitz claims cures of about 60 per cent of ulcer with medical treatment, but both the callous and the non-callous ulcers may remain uncured. König, like many others, is swinging from gastroenterostomy to the radical operations, which in experienced hands, he says, may give a mortality as low as 3 per cent.

Morawitz, who contributes the fourth article himself, insists that the medical and surgical treatment need not conflict, for if we adhere to the former we are practically certain of curing 55 to 60 per cent of the patients, this figure being also likely to be bettered in the future. We still have surgery to fall back on, when indication arises, which will give us 85 per cent of radical cures.

THE CHIROPRACTOR AND THE DRUGLESS PRACTITIONER

What is the practice of medicine? Why is it that those who practice it are the natural enemies of quackery and charlatanism, through which, under the guise of miraculous cures, avaricious imposters trade upon the credulity of the ignorant?

The second question is answered by a close analysis of the first. Let us employ Webster's Dictionary. "Medicine" is defined "as the science which relates to the prevention, cure or alleviation of disease." "Science" is "ascertained truth" or "accumulated and established knowledge." "Practice" is the "application of science to the wants of men." Applying these definitions, the practice of medicine may be defined as the application of ascertained truth and established knowledge to the prevention, cure or alleviation of human diseases.

Chiropractic, "drugless practice" and allied and similar fallacies are opposed by the legitimate practitioners of medicine for the simple reason that the unproven theories upon which they rest are not based upon "ascertained truth" or "established knowledge." The followers of these cults have not subjected and would not dare to subject, the doctrine which they profess to scientific scrutiny or analysis—to the test by which their truth or falsity could be scientifically "ascertained."

The reason why "medicine" is defined as "science" is because it rests on "ascertained truth" and "established knowledge." "Medicine" does not rest upon the mere assertion of the truths which underlie it, but upon the fact that that which it asserts as "truth" has been "ascertained." The charlatan substitutes declamation and assertion for "ascertained truth." Whether his assertion be true or false is of indifference to him provided, by making the assertion, he can secure enough paying followers to believe in him and that which he asserts.

There is nothing more truly progressive than the mind of the scientist. He is eager for new knowledge, is constantly searching for it, and having found it is quick to employ it, but before he is ready to accept it as knowledge, or to act upon it or to advise others to act upon it, the truth underlying this new knowledge must be scientifically tested and established—it must be "ascertained."

In our last editorial we reviewed the pending chiropractic bill and showed how it was in-

tended thereunder to waive examination for practically all those now practicing spinal manipulation. Another measure pending before the legislature is a bill introduced by Mr Lambert, January 25, 1926, Print No 437, Introductory No 438, relating to "drugless practice."

It is unnecessary here to analyze the truth or falsity of this method of treating human disease—a method which is defined by the bill as "based on the science derived from knowledge of the aggregate of all the natural and mechanical methods such as the manipulation of the body including the spine, the application of light, heat, water, air, diet, mechanical apparatus and electricity in the treatment of disease and removal of abnormalities of the body without the use of drugs, medicine, surgery, osteopathy, obstetrics or Christian Science." Whether, in the treatment of certain types of disease, the application of these agencies by trained scientific men may be of value is a question which does not require analysis at this time, for the reason that the proposed bill seeks to admit, by the familiar waiver method, all those who are now engaged in "drugless practice."

Section 285-1 provides that "any person twenty-one years of age who is of good moral character, who for at least *twelve years* prior to January 1st, 1926, has practiced drugless methods exclusively" within the State, or drugless practitioners "who for at least *nine years*" have so practiced, having a diploma from a legally incorporated school or college of drugless methods, or drugless practitioners "who for at least *six years* prior" to said date have so practiced and have a similar diploma from such a school "requiring a residence course of study", or drugless practitioners "who for at least *three years* prior" to said date, have so practiced and have similar diplomas from such school or college "requiring a residence course of at least twelve months", or drugless practitioners who have so practiced and are graduates from such school requiring a residence course of at least eighteen months, "may within one month after this act goes into effect, *without examination* and upon payment of the sum of twenty-five dollars to the board, receive from the board a certificate, which, when presented to the regents, shall entitle such person to a license to practice drugless methods, as though such examination had been taken and successfully passed and then

certified by the regents. The State Board of Regents shall issue a license to practice drugless methods to all those certified by the Board.

In this bill, as in the chiropractic bill discussed in our last editorial, certain educational requirements and examinations are required of those who hereafter desire to practice drugless healing, but in the meantime either all or a very large number of those now engaged in such practice and who have not been subjected to the test of any State examination but have complied with the provisions of the section quoted, will become entitled to a license.

This bill, the chiropractic bill, and similar measures, through the guise of educational requirements and examinations for those hereafter to be admitted, seek to license, by a general waiver or amnesty provision, those who are now engaged in the practice of their particular cults—that is, those who are now illegally practicing medicine as defined by the Public Health Law.

It is the elementary duty of the legislature to protect, preserve and safeguard the public health. It is its duty to defend the people of the State against imposition and to entrust the care and treatment of disease to those only whose fitness and knowledge have been ascertained and tested by the State. The primary duty of the law-making body is to consider the public health and not to provide a method by which untrained

and incompetent men may be turned loose to prey upon human credulity and ignorance.

Who is more competent to advise the legislature in these matters than those who themselves have been subjected to rigid tests of State examinations and have been devoting their lives, their strength and their minds to the ascertainment of scientific knowledge and to the proper application of that knowledge to the cure, prevention and alleviation of human pain and suffering? Those who feel the call to practice medicine engage in long, laborious and difficult study, the knowledge which they acquire from this study is thoroughly tested by the State. That is as it should be. Life is short and science is long. No study is too much. Why, then, should an army of men be licensed and admitted to practice, whether the practice be called "chiropractic," "drugless practice" or by some other name, who have not engaged in this study, have not mastered the science of medicine, have not been subjected to State examinations, and have not demonstrated the possession of that knowledge and training which it is essential they should possess if the health and welfare of the human race is to be adequately safeguarded and protected? Every legitimate effort should be expended for the prevention of the passage of the drugless practice bill.

ACTION FOR SERVICES RENDERED—MALPRACTICE COUNTERCLAIM

A physician having rendered professional service to a patient and thereafter having rendered various bills for such service and the same not being paid, he instituted an action for the collection of his bill. His complaint in this action was met with a general denial, except the defendant admitted that certain services were rendered. The defendant likewise, as a means of avoiding the payment of the physician's bill, interposed a counterclaim of alleged malpractice, charging that the physician was engaged to attend and treat an abscess on the left side of the body, that he failed to make a proper examination and likewise failed properly to attend, prescribe and care for the condition, and that by reason of such negligence the collapse of the patient was caused and she was obliged to spend a period of about

five months in a sanitarium under the care of physicians and nurses until the condition was cured and she was restored to health.

Upon the receipt of the counterclaim a motion was made to dismiss the complaint on the ground that it being an action of alleged malpractice it was barred by the two-year statute of limitations, which motion was granted. It was argued by the patient that the counterclaim was based upon breach of contract and therefore fell under the six-year statute of limitations. This contention was not sustained by the court, it holding that the claim was one of malpractice and barred by the two-year statute of limitations. The motion to dismiss was granted and the physician was then enabled to collect his bill.

State Department of Health

Fewer People Die of Old Age

Forty years ago, almost 5,000 deaths in the State were attributed to "old age." Last year the number of deaths under this rubric was only 610, a decrease of almost 90 per cent. The number of deaths from all causes has increased 75 per cent in this period of time. What is the reason for the astonishing decrease in mortality from "old age"?

Most of the deaths under this rubric fall in the age group "70 years and over," although some deaths are attributed to senility at earlier ages, occasionally even in early middle life. The population of the State has doubled and the number of old people has more than doubled since 1885. The decrease in the number of deaths from old age is therefore not due to a shrinking in the contingent of the population from which these deaths are drawn. The reason for this change lies in the more careful and scientific diagnosis of the cause of death. Where forty years ago, because of indifferent reporting or for want of knowledge the death of an old person was often attributed simply to the effects of old age, now an effort is made to establish a definite diagnosis in every case. The progressive reduction in deaths under this head marks the growing skill and attention on the part of the practicing physicians of the State.

Are Gonorrhea and Syphilis Decreasing in the Rural Districts?

The incidence of gonorrhea and syphilis as reported upstate has always been very low in the rural as compared with the urban districts. It has frequently been pointed out that there is no conclusive evidence that the actual incidence is less in the rural districts than in the urban districts and the difference in the morbidity rates has been attributed to such factor as, (a) people residing in rural districts seeking treatment in the city and giving a city address, (b) a less careful searching in the rural districts than in the city for hidden cases of syphilis when it is not reported, (c) a lack of diagnostic facilities in the rural towns and villages, (d) a lack of clinic having found the country districts for the treatment of these diseases. However, all of these factors to act upon it originate as far as known to the same it, the truth underlying from the time the statistics be scientifically tested. Yet the percentage of cases he be "ascertained" is low, where the incidence is low.

In our last editorial we fell from 1951 to 1925. The following table will show the consistent decrease in the proportion of total cases classified as rural.

98 in 1925. There has been an equally consistent decrease in the percentage of total cases of syphilis for the rural districts, namely, a decrease from 17.1 per cent in 1921 to 7.5 per cent in 1925. The following table will show the consistent decrease in the proportion of total cases classified as rural.

Per Cent of Total Cases in Rural Districts

	Gonorrhea	Syphilis
1921	19.5	17.1
1922	16.7	15.5
1923	12.4	10.5
1924	12.0	9.5
1925	9.8	7.5

Not only has the percentage of the total cases decreased, but the absolute number of cases has fallen off materially. The number of cases of gonorrhea dropped from 759 in 1921 to 452 in 1925, and for syphilis from 1,667 in 1921 to 980 cases in 1925. During this same period, the absolute number of cases for the urban districts has increased 33 1/3 per cent in the cases of gonorrhea and 50 per cent in the case of syphilis.

Trichinosis.

Recently, there occurred in Syracuse and Rochester several cases of trichinosis. Dr. Silverman, director of the Bureau of Communicable Diseases of the Syracuse Department of Health, stated that there had been five mild cases in that city. Four of these occurred in one family, the diagnosis having been made on clinical symptoms and eosinophilia. In the other case trichinae were found in the blood. Three of the cases were first reported as typhoid suspects. Sausages were suspected as the source of infection, but examination of the suspect material was negative.

Dr. G. W. Goltsch reported a similar case of trichinosis in Ithaca. The diagnosis had been made on clinical findings and eosinophilia. In one case the blood stream contained trichinae. In three cases the patients had eaten raw ham from a market. In two cases the patients had eaten sausages at a social trip. Pork was found with five trichinae.

LEGISLATION

HENRY L. K. SHAW, M.D.
Chairman Committee on Legislation

MEETING OF CHAIRMEN OF COUNTY LEGISLATIVE COMMITTEES

A meeting and conference of the Chairmen of the Legislative Committees of the County Medical Societies was held at noon on Wednesday, February 10, in the Ten Eyck Hotel, Albany. Dr. H. L. K. Shaw, Chairman of the Committee on Legislation of the Medical Society of the State of New York, presided. Although the weather was inclement and a snowstorm was raging, delegates were present from all parts of the State, representing approximately the same number of counties as in previous years.

The conference began with a luncheon at which the committeemen became acquainted with one another and received preliminary information on the political situation in respect to medical bills. After the luncheon Dr. Shaw introduced Hon. Frank H. Lattin, Chairman of the Assembly Committee in Public Health, Hon. Charles P. Miller, Chairman of the Assembly Committee on Labor and Industry, and Hon. R. H. Loomis, who will sponsor the Medical Practice Act in the Assembly, Mr. Lloyd P. Stryker, Counsel of the Medical Society of the State of New York, Dr. N. B. Van Etten, President of the State Society, and Dr. Augustus Downing, Assistant Commissioner of Education.

The principal object of the conference was the discussion of legislative bills which were related to public health. A typewritten memorandum of thirty-seven bills, with brief comments on their nature, was given to each member. Many of the bills were almost identical with those of last year. Fifteen related to workmen's compensation, and five to cult practice. The memorandum is printed on page 204 of this Journal.

A large part of the conference was devoted to the consideration of the Practice of Medicine bill. This bill was drawn by a special committee which was authorized by the House of Delegates in 1925 for the special purpose of creating a bill which should represent the desires of the doctors of New York State. The committee held meetings almost weekly during the Summer and early Fall, and its members agreed on certain broad principles which the physicians wished to put into effect. The bill that was written by the committee of doctors was printed in the November 1, 1925, issue of this Journal. After the doctors had completed the first draft, the bill was submitted to the Counsel of the State Medical Society and then to the regents of the State of New York, both of whom made suggestions and changes in order to adapt the bill

to the law, the Constitution, and to the established customs and methods of administration. However, nearly all the main features of the bill were left intact, and the finished product is the combined work of the doctors, the lawyers, and the Education Department. The revised bill is printed on page 208 of this Journal.

Several physicians representing sections that were opposed to registration in former years spoke in favor of the bill. At the end of the discussion a motion was made that the conference support the Practice of Medicine bill as it was presented and the motion was carried.

Dr. Shaw announced that the Practice of Medicine bill will be introduced in the Legislature within a few days. The special features of this bill are as follows:

- (a) Registration annually while in practice,
- (b) Legality of license not to be affected by failure to register,
- (c) Clear definition as to who may practice and when, while not licensed in the State,
- (d) Doctor of Medicine never to be conferred as an honorary title,
- (e) Penalties—Use of title "Doctor" to be limited to physicians,
- (f) Attorney General to prosecute violators,
- (g) Grievance Committee Professional barrier to help the physician protect himself against blackmail.

A large part of the time of the conference was devoted to a discussion of the Workmen's Compensation bill, Assembly Introductory Number 65, Concurrent Senate Introductory Number 35 known as the Miller Bill. This bill embodies the suggestions of Dr. W. W. Britt, Chairman of the Committee on Economics, and Dr. H. P. Hourigan, Chairman of the special committee on Workmen's Compensation. These two doctors consulted with Hon. Charles P. Miller, Chairman of the Assembly Committee on Labor and Industry, who is a recognized authority on workmen's compensation, and the three have devised a law which should meet the doctors' objections of the present methods of settling compensation cases. The bill amends the present Labor Law by creating four authoritative bodies.

- 1 A State Medical Advisory Council of five members
- 2 District Medical Advisory Councils, each of five members
- 3 A State Medical Director and a Deputy Director
- 4 Medical examiners

The State Medical Advisory Council and the District Councils shall hear and adjudicate cases in which there is a dispute regarding medical conditions and findings. The present method is that lay boards shall hear and pass upon conditions which are purely medical, and in doing so, physicians are heard first on one side and then on the other and the boards decide between medical opinions which are often conflicting. The new law provides the machinery by which medical men shall decide questions of medicine, and will thereby prevent the dissatisfaction which doctors often express regarding the medical decisions of lay boards.

Dr Hourigan explained the provisions of the proposed law and urged the physicians to accept a share of the responsibility of the administration of the Workmen's Compensation law, especially in deciding whether or not one man is right and another is wrong on a medical question affecting compensation.

The administration of the Workmen's Compensation law will be further clarified by the passage of Assembly Introductory Bill Number 515 and Senate Introductory Bill Number 250. This bill creates a Board of Review and a Council of Industrial Standards and Appeals. The two bodies are made responsible for rules and regulations regarding the administration of the Workmen's Compensation Law, and for the execution of the law and unifying the existing procedures. This bill will do for Workmen's Compensation cases generally what the Miller Bill will do for the medical phases of the cases.

MEMORANDUM OF BILLS SUBMITTED TO THE CONFERENCE OF CHAIRMEN OF COUNTY LEGISLATIVE COMMITTEES

FIFTEEN WORKMEN'S COMPENSATION BILLS

MEDICAL COUNCILS

Assembly Introductory No 65—concurrent Senate Introductory No 35—known among us as the Miller Bill, attempts to reorganize the medical division of the Department of Labor and Industries by providing for the appointment of a director and deputy director, a State council and district councils—who shall have complete charge of all medical work. Those appointed to any the above positions shall be selected from a list of candidates named by the Medical Society of the State of New York. Opposition to this bill is slow in developing, probably there will not be a great deal. Dr Britt, chairman of the Committee on Economics, and Dr Hourigan, chairman of the special Committee on Workmen's Compensation, collaborated with Assemblyman Miller in drafting this bill.

PERCENTAGES OF LOSS OF EYESIGHT

Assembly Introductory No 331—concurrent Senate Introductory No 184 and Assembly Introductory No 364—concurrent Senate Introductory No 141—provide for the proper determination of the percentage of loss of efficiency of eyesight. In No 331, Assemblyman Miller has incorporated the recommendations of the special committee appointed by the American Medical Association to devise the best way of determining the method of computing the degree of loss in sight efficiency due to eye injuries.

CONDITIONS OF COMPENSATION

Assembly Introductory No 18 would amend the present law so as to make compensation available only where the injuries arise in the duties. The law now reads, "out of and in."

LIST OF DISABLING DISEASES

Assembly Introductory No 79—concurrent Senate Introductory No 465—adds to the list of specified disabling diseases a general clause stating that persons suffering from any and all disabling diseases and disabling illnesses, and while occupied in any and all employments enumerated before, shall be eligible to compensation.

TIME FOR REPORTING CLAIMS

Assembly Introductory No 231—concurrent Senate Introductory No 110—would amend the law removing the stipulation which made it absolutely necessary that claim for medical or surgical treatment be reported within twenty days following the first treatment.

BENZINE POISONING

Assembly Introductory No 235—concurrent Senate Introductory No 98—would add to the list of occupational diseases such as may occur from poisoning by benzine or any of its derivatives.

COAL TAR POISONING

Assembly Introductory No 236—concurrent Senate Introductory No 99—would add poisoning by coal tar or any of its derivatives to the list of occupational diseases.

SILICOSIS

Assembly Introductory No 245—concurrent Senate Introductory No 118—adds the Miller silicosis bill of last year, and would add silicosis to the list of occupational diseases.

MEDICAL COSTS

Assembly Introductory No 251—concurrent Senate Introductory No 106—provides that the term "compensation" shall be interpreted to include medical costs

TIME FOR MAKING CLAIMS

Assembly Introductory No 254—concurrent Senate Introductory No 120—describes how a claim may be entered even at the expiration of two years

PERCENTAGE OF DISABILITY

Assembly Introductory No 279—concurrent Senate Introductory No 143—defines how the percentage of loss in efficiency of an arm shall be determined when a finger is removed

CONSENTS FOR MEDICAL SERVICES

Assembly Introductory No 283—concurrent Senate Introductory No 138—would amend the law by deleting that portion which made it necessary for the employee to consult the employer before securing medical attention and requiring the physician to furnish the employer and the industrial commissioner a report of such injury within twenty days of the time of the first treatment—and by inserting a section authorizing the employee to secure medical, surgical or other attendance or treatment, nurse and hospital service, medicine, crutches and apparatus, without consulting the employer in such service is required immediately and the employer is not available. It further requires that expenses incurred in such way must be paid by the employer

COMPENSABLE DISABILITIES

Assembly Introductory No 368—concurrent Senate Introductory No 147—would add to the present law, in which 19 occupational diseases are mentioned, a clause including all other occupational diseases not before enumerated as included with those for which compensation may be paid

BOARD OF REVIEW AND COUNCIL OF INDUSTRIAL STANDARDS AND APPEALS

Assembly Introductory No 515—concurrent Senate Introductory No 250—aims to amend

the Labor Law generally by abolishing the Industrial Board and creating a Board of Review for Workmen's Compensation and a Council of Industrial Standards and Appeals. The Board of Review for Workmen's Compensation shall consist of five members appointed by the Governor, one of whom shall be designated by the Governor as chairman. It shall have the power to make, amend and repeal rules governing the practice and procedure under the Workmen's Compensation Law. On application of any party, or on its own motion, it may review and determine all claims for compensation, and shall have power to require medical service for injured employees, to approve claims for medical service or attorney's fees, etc. The Council of Industrial Standards and Appeals shall consist of a councilor and two other members appointed by the Board of Review for Workmen's Compensation. It shall have power to make, amend and repeal rules for carrying into effect the provisions of this chapter, to test materials, to approve or disapprove devices, apparatus, or machinery guards, to make such investigations or inquiries as may be necessary for the proper performance of its duties, to suggest amendments to the law to the commissioner

RECOVERING COSTS OF TREATMENT

Assembly Introductory No 613 would amend the Workmen's Compensation Law by providing that an injured employee shall be entitled to recover, as part of the compensation, all reasonable amounts expended for medical, surgical or other attendance or treatment, nurses and hospital service, medicine, crutches and apparatus, providing the physician furnish to the employer and the industrial commissioner, within twenty days following the first treatment, a report of the injury and treatment. Also providing that if the injured employee fails for a period of five days to provide for himself such medical, surgical or other attendance, the employer shall promptly thereafter provide for the same

FIVE CULTIST BILLS

THE ESMOND CHIROPRACTIC BILL

Assembly Introductory No 153 is the Esmond Chiropractic bill. You will note that Esmond has endeavored to make his bill acceptable by providing that, in the future, none shall be licensed to practice chiropractic unless he takes an examination in the fundamental branches under the Board of Regents at the same time that those seeking a license for the practice of medicine are examined. This bill has two outstanding faults, the first point will be attacked

by the osteopaths, because they are obliged to show 28 months of study in four years, while Esmond has provided for only 24 months. The bill is attacked by all of us. He claims that his bill will exempt from examination but 30 chiropractors. The Fearon bill last year claimed that it would exempt fewer than 200, and Mr Esmond feels, therefore, that his bill should be more acceptable than the Fearon bill was. Of course, there is a great doubt as to whether Esmond knows how many men would be eligible for such

- 1 A State Medical Advisory Council of five members
- 2 District Medical Advisory Councils, each of five members
- 3 A State Medical Director and a Deputy Director
- 4 Medical examiners

The State Medical Advisory Council and the District Councils shall hear and adjudicate cases in which there is a dispute regarding medical conditions and findings. The present method is that lay boards shall hear and pass upon conditions which are purely medical, and in doing so, physicians are heard first on one side and then on the other, and the boards decide between medical opinions which are often conflicting. The new law provides the machinery by which medical men shall decide questions of medicine, and will thereby prevent the dissatisfaction which doctors often express regarding the medical decisions of lay boards.

Dr Hourigan explained the provisions of the proposed law and urged the physicians to accept a share of the responsibility of the administration of the Workmen's Compensation law, especially in deciding whether or not one man is right and another is wrong on a medical question affecting compensation.

The administration of the Workmen's Compensation law will be further clarified by the passage of Assembly Introductory Bill Number 515 and Senate Introductory Bill Number 250. This bill creates a Board of Review and a Council of Industrial Standards and Appeals. The two bodies are made responsible for rules and regulations regarding the administration of the Workmen's Compensation Law, and for the execution of the law and unifying the existing procedures. This bill will do for Workmen's Compensation cases generally what the Miller Bill will do for the medical phases of the cases.

MEMORANDUM OF BILLS SUBMITTED TO THE CONFERENCE OF CHAIRMEN OF COUNTY LEGISLATIVE COMMITTEES FIFTEEN WORKMEN'S COMPENSATION BILLS

MEDICAL COUNCILS

Assembly Introductory No 65—concurrent Senate Introductory No 35—known among us as the Miller Bill, attempts to reorganize the medical division of the Department of Labor and Industries by providing for the appointment of a director and deputy director, a State council and district councils—who shall have complete charge of all medical work. Those appointed to any the above positions shall be selected from a list of candidates named by the Medical Society of the State of New York. Opposition to this bill is slow in developing, probably there will not be a great deal. Dr Britt, chairman of the Committee on Economics, and Dr Hourigan, chairman of the special Committee on Workmen's Compensation, collaborated with Assemblyman Miller in drafting this bill.

PERCENTAGES OF LOSS OF EYESIGHT

Assembly Introductory No 331—concurrent Senate Introductory No 184 and Assembly Introductory No 364—concurrent Senate Introductory No 141—provide for the proper determination of the percentage of loss of efficiency of eyesight. In No 331, Assemblyman Miller has incorporated the recommendations of the special committee appointed by the American Medical Association to devise the best way of determining the method of computing the degree of loss in sight efficiency due to eye injuries.

CONDITIONS OF COMPENSATION

Assembly Introductory No 18 would amend the present law so as to make compensation available only where the injuries arise in the duties. The law now reads, "out of and in."

LIST OF DISABLING DISEASES

Assembly Introductory No 79—concurrent Senate Introductory No 465—adds to the list of specified disabling diseases a general clause stating that persons suffering from any and all disabling diseases and disabling illnesses, and while occupied in any and all employments enumerated before, shall be eligible to compensation.

TIME FOR REPORTING CLAIMS

Assembly Introductory No 231—concurrent Senate Introductory No 110—would amend the law removing the stipulation which made it absolutely necessary that claim for medical or surgical treatment be reported within twenty days following the first treatment.

BENZINE POISONING

Assembly Introductory No 235—concurrent Senate Introductory No 98—would add to the list of occupational diseases such as may occur from poisoning by benzine or any of its derivatives.

COAL TAR POISONING

Assembly Introductory No 236—concurrent Senate Introductory No 99—would add poisoning by coal tar or any of its derivatives to the list of occupational diseases.

SILICOSIS

Assembly Introductory No 245—concurrent Senate Introductory No 118—is the Miller silicosis bill of last year, and would add silicosis to the list of occupational diseases.

use by licensed pharmacists or druggists of any regular preparation containing alcohol other than whiskey and brandy

INCOME TAX

Assembly Introductory No 376—concurrent Senate Introductory No 85—would amend the Tax Law, allowing the deduction from income of all expenses paid or incurred during the taxable year for medical, surgical, or dental services, unless the net income exceeds \$5,000 00

EDUCATION DEPARTMENT

Senate Introductory No 411 is a reintroduction of a bill that was submitted by the Department of Education last year. It was revised toward the end of the year, and this is an exact reproduction of the latest revision

ENDORSEMENT OF PHYSICIANS' LICENSES

Assembly Introductory No 132 provides that persons having received a license in another State after graduation from a registered medical school prior to August 1, 1900, and have practiced their profession in another State or States for fifteen years or more, shall, without further examination on payment of \$25 00 to the Regents, receive endorsement of their licenses to practice in this State

DEPARTMENT OF HEALTH DIVISION OF RURAL HYGIENE

Assembly Introductory No 327—concurrent Senate Introductory No 49—provides for the creation in the Department of Health of a Division of Rural Hygiene and appropriates \$10,000 00 for that purpose. It is our understanding that this bill originated with the Grange. It was introduced last year and, although it failed of passage, there was no noticeable opposition to it

HEALTH OFFICERS

Assembly Introductory No 389 was introduced by the Department of Health and would amend the law concerning the duties of health officer, allowing him compensation for special duties such as caring for epidemics and also the taking of cultures for releasing cases of diphtheria, and would further amend it by inserting a clause permitting the health officer to appoint a substitute to serve as acting health officer during the time of his incapacitation or absence from office

EYE GLASSES FOR SCHOOL CHILDREN

Assembly Introductory No 497 would oblige the school board or other proper authority to provide, free of charge, eye glasses for children found to need them and who are not able to pay for the same. Last year Mr Mandelbaum introduced this bill as an amendment to the Greater New York charter and to apply to New York City alone but it failed of passage and this year he has introduced it as an amendment to the Education Law, making it State wide

MEDICAL EXAMINATIONS OF PRISONERS IN COUNTY JAILS

Assembly Introductory No 552—concurrent Senate Introductory No 375—This bill originated with the Prison Commission. For more than five years the Prison Commission has been endeavoring to secure the examination of prisoners when entered to the county jails. A stimulus for this came from the venereal and tuberculosis campaigns, but it has gradually developed until at present the Commission thinks that every person entered to a county jail should receive the same sort of careful physical examination as is given those entered to the penitentiaries, Ossining or Auburn. The bill will very likely develop considerable opposition from the county authorities, because it will mean that the physician appointed for that work will want a definite increase in his salary. At the present time some are paid as little as \$50 00 a year and, of course, they give only such attention as is absolutely required, but in the last couple of years some supervisors have been persuaded to increase the salary of the physicians with the understanding that they will undertake this additional work. It will be expected that these counties will support the move, but they are a small minority. The principal opposition to the bill will very likely be based on economy

PREVENTION OF HEREDITARY BLINDNESS

Assembly Introductory No 595 would amend the Domestic Relation Law by adding a new section on prevention of hereditary blindness. It requires the city clerk, before granting a marriage license, to secure a written statement from both parties to the effect that, to the best of their knowledge and belief, none of their blood relatives within the second degree has been affected with blindness, or, if so, that they have submitted to an examination by the family physician or an expert in heredity. If one of the applicants refuses or fails to make such statement, or if the clerk is not satisfied of the truth of the statements, he shall refuse to grant a license unless the applicant file a bond on the condition that if any child is born of the marriage and becomes a public charge on account of an inherited blindness, the cost of the support of the child up to the whole amount of the bond, not to exceed \$14,000 00, shall be paid to the State of New York to be applied to the support of the child

SITES OF TUBERCULOSIS HOSPITALS

Assembly Introductory No 347 would amend the law concerning the securing of a site for a tuberculosis hospital by making it possible for the Commissioner of Health to refuse any part of a site at any time prior to its actual occupancy

exemption And, then, the question always arises as to the interest the public should have in allowing any unqualified man the privilege of assuming the responsibility for life and death

DRUGLESS THERAPY BILL

Assembly Introductory No 437—concurrent Senate Introductory No 97—is the drugless therapy bill which Senator Gibbs sponsored last year in the Senate Assemblyman Lambert, of Niagara County, was persuaded to introduce the bill into the Assembly this year A few changes have been made in it, but it is practically the bill that we considered last year and should not get out of committee

LICENSING PHYSICIANS AND HEALERS

Assembly Introductory No 71 would amend the Penal Law, making it unlawful for any person to practice as a physician or healer or to hold himself out to the public as being entitled to practice medicine or healing or to assume to be a physician or healer, or advertise the title of doctor, physician or healer in such manner as to convey the impression that he is a legal practitioner of medicine or healing, without having first been duly and regularly licensed and admitted to practice as a physician or healer under the laws of this State The apparent aim of this amendment is to prevent any but licensed physicians from caring for the sick, and includes among its opponents, therefore, Christian Scientists, chiropractors, drugless therapists and all cultists Unfortunately, this bill is poorly drafted, in that it assumes that the State has licensed, in addition to physicians, a group known as healers, and refers to this group by excepting those legally licensed as such From this objec-

tion, alone, the bill very likely will not get out of committee

DEFINITION OF PRACTICE OF MEDICINE

Assembly Introductory No 690 aims to rewrite the definition of the "practice of medicine" Under the present law a person is practicing medicine when he holds himself out as being able to diagnose, treat, operate, or prescribe for any human disease, pain, injury, deformity, or physical condition, and who shall either offer or undertake by any means or method to diagnose, treat, operate, or prescribe for any human disease, pain, injury, deformity, or physical condition The amendment, as is readily seen, would limit the application to those who prescribe and administer medicine or drugs and perform surgical operations under anaesthesia This attempt at revision tries to interpret the practice of medicine as meaning the use of drugs and not the diagnosis and care of the sick person It is plain that the author of the bill had in mind the claim of the chiropractors that they are not practicing medicine in the true sense of the word and should not be amenable to the laws laid down for physicians

PODIATRY

Assembly Introductory No 417 There was a bill introduced last year aiming to prevent the chiropodists and podiatrists from advertising themselves as other than they really are It was specifically stated that they were to be prohibited from using such terms as "foot specialist," "surgeon" and "orthopedic specialist," but last year's bill did not have the additional clause which Mr Jenks has added this year, permitting the podiatrists to use the title "doctor"

MISCELLANEOUS BILLS

COMPULSORY HEALTH INSURANCE

Assembly Introductory No 22 is a compulsory health insurance bill Mr Cuvillier reintroduced the bill of 1922 practically with no modifications This bill has not as yet been introduced to the Senate, and probably will not get any farther

OPTOMETRY

Assembly Introductory No 499 makes it illegal for optometrists to advertise in violation of rules to be promulgated by the Board of Regents

HABIT FORMING DRUGS

Assembly Introductory No 557—concurrent Senate Introductory No 357—is the Habit Forming Drug bill of last year It is an exact reproduction of the bill as it was revised at the end of the session It met with our approval then and I presume that our attitude should be the same this year The principal opposition to this bill in the past has come from manufactur-

ers of patent medicines, particularly establishments in Norwich and Rochester

DRUG ADDICTS

Assembly Introductory No 558—concurrent Senate Introductory No 391—would license private institutions where drug addicts are admitted This is an exact copy of a bill introduced last year by Mr Weinfeld His bill died in committee, and I do not know why Dr Vander Veer approved of the bill and wrote to the committee urging its passage

REGISTRY OF PHARMACIES

Assembly Introductory No 594 would amend the pharmacy law, providing that pharmacies, drug stores or other stores having a license or permit to sell or dispose of intoxicating liquors shall not be registered in the manner prescribed by law for the registering of pharmacies, but does not prohibit the lawful possession, sale and

use by licensed pharmacists or druggists of any regular preparation containing alcohol other than whiskey and brandy

INCOME TAX

Assembly Introductory No 376—concurrent Senate Introductory No 85—would amend the Tax Law, allowing the deduction from income of all expenses paid or incurred during the taxable year for medical, surgical, or dental services, unless the net income exceeds \$5,000 00

EDUCATION DEPARTMENT

Senate Introductory No 411 is a reintroduction of a bill that was submitted by the Department of Education last year. It was revised toward the end of the year, and this is an exact reproduction of the latest revision

ENDORSEMENT OF PHYSICIANS' LICENSES

Assembly Introductory No 132 provides that persons having received a license in another State after graduation from a registered medical school prior to August 1, 1900, and have practiced their profession in another State or States for fifteen years or more, shall, without further examination on payment of \$25 00 to the Regents, receive endorsement of their licenses for practice in this State

DEPARTMENT OF HEALTH DIVISION OF RURAL HYGIENE

Assembly Introductory No 327—concurrent Senate Introductory No 49—provides for the creation in the Department of Health of a Division of Rural Hygiene and appropriates \$10,000 00 for that purpose. It is our understanding that this bill originated with the Grange. It was introduced last year and, although it failed of passage, there was no noticeable opposition to it

HEALTH OFFICERS

Assembly Introductory No 389 was introduced by the Department of Health and would amend the law concerning the duties of health officer, allowing him compensation for special duties such as caring for epidemics and also the taking of cultures for releasing cases of diphtheria, and would further amend it by inserting a clause permitting the health officer to appoint a substitute to serve as acting health officer during the time of his incapacitation or absence from office

EYE GLASSES FOR SCHOOL CHILDREN

Assembly Introductory No 497 would oblige the school board or other proper authority to provide, free of charge, eye glasses for children found to need them, and who are not able to pay for the same. Last year Mr Mandelbaum introduced this bill as an amendment to the Greater New York charter and to apply to New York City alone but it failed of passage and this year he has introduced it as an amendment to the Education Law, making it State wide

MEDICAL EXAMINATIONS OF PRISONERS IN COUNTY JAILS

Assembly Introductory No 552—concurrent Senate Introductory No 375—This bill originated with the Prison Commission. For more than five years the Prison Commission has been endeavoring to secure the examination of prisoners when entered to the county jails. A stimulus for this came from the venereal and tuberculosis campaigns, but it has gradually developed until at present the Commission thinks that every person entered to a county jail should receive the same sort of careful physical examination as is given those entered to the penitentiaries, Ossining or Auburn. The bill will very likely develop considerable opposition from the county authorities, because it will mean that the physician appointed for that work will want a definite increase in his salary. At the present time some are paid as little as \$50 00 a year and, of course, they give only such attention as is absolutely required, but in the last couple of years some supervisors have been persuaded to increase the salary of the physicians with the understanding that they will undertake this additional work. It will be expected that these counties will support the move, but they are a small minority. The principal opposition to the bill will very likely be based on economy

PREVENTION OF HEREDITARY BLINDNESS

Assembly Introductory No 595 would amend the Domestic Relation Law by adding a new section on prevention of hereditary blindness. It requires the city clerk, before granting a marriage license, to secure a written statement from both parties to the effect that, to the best of their knowledge and belief, none of their blood relatives within the second degree has been affected with blindness, or, if so, that they have submitted to an examination by the family physician or an expert in heredity. If one of the applicants refuses or fails to make such statement, or if the clerk is not satisfied of the truth of the statements, he shall refuse to grant a license unless the applicant file a bond on the condition that if any child is born of the marriage and becomes a public charge on account of an inherited blindness, the cost of the support of the child up to the whole amount of the bond, not to exceed \$14,000 00, shall be paid to the State of New York to be applied to the support of the child

SITES OF TUBERCULOSIS HOSPITALS

Assembly Introductory No 347 would amend the law concerning the securing of a site for a tuberculosis hospital by making it possible for the Commissioner of Health to refuse any part of a site at any time prior to its actual occupancy

exemption And, then, the question always arises as to the interest the public should have in allowing any unqualified man the privilege of assuming the responsibility for life and death

DRUGLESS THERAPY BILL

Assembly Introductory No 437—concurrent Senate Introductory No 97—is the drugless therapy bill which Senator Gibbs sponsored last year in the Senate Assemblyman Lambert, of Niagara County, was persuaded to introduce the bill into the Assembly this year A few changes have been made in it, but it is practically the bill that we considered last year and should not get out of committee

LICENSING PHYSICIANS AND HEALERS

Assembly Introductory No 71 would amend the Penal Law, making it unlawful for any person to practice as a physician or healer or to hold himself out to the public as being entitled to practice medicine or healing or to assume to be a physician or healer, or advertise the title of doctor, physician or healer in such manner as to convey the impression that he is a legal practitioner of medicine or healing, without having first been duly and regularly licensed and admitted to practice as a physician or healer under the laws of this State The apparent aim of this amendment is to prevent any but licensed physicians from caring for the sick, and includes among its opponents, therefore, Christian Scientists, chiropractors, drugless therapists and all cultists Unfortunately, this bill is poorly drafted, in that it assumes that the State has licensed, in addition to physicians, a group known as healers, and refers to this group by excepting those legally licensed as such From this objec-

tion, alone, the bill very likely will not get out of committee

DEFINITION OF PRACTICE OF MEDICINE

Assembly Introductory No 690 aims to rewrite the definition of the "practice of medicine" Under the present law a person is practicing medicine when he holds himself out as being able to diagnose, treat, operate, or prescribe for any human disease, pain, injury, deformity, or physical condition, and who shall either offer or undertake by any means or method to diagnose, treat, operate, or prescribe for any human disease, pain, injury, deformity, or physical condition. The amendment, as is readily seen, would limit the application to those who prescribe and administer medicine or drugs and perform surgical operations under anæsthesia This attempt at revision tries to interpret the practice of medicine as meaning the use of drugs and not the diagnosis and care of the sick person It is plain that the author of the bill had in mind the claim of the chiropractors that they are not practicing medicine in the true sense of the word and should not be amenable to the laws laid down for physicians

PODIATRY

Assembly Introductory No 417 There was a bill introduced last year aiming to prevent the chiropodists and podiatrists from advertising themselves as other than they really are. It was specifically stated that they were to be prohibited from using such terms as "foot specialist," "surgeon" and "orthopedic specialist," but last year's bill did not have the additional clause which Mr Jenks has added this year, permitting the podiatrists to use the title "doctor"

MISCELLANEOUS BILLS

COMPULSORY HEALTH INSURANCE

Assembly Introductory No 22 is a compulsory health insurance bill Mr Cuvillier reintroduced the bill of 1922 practically with no modifications This bill has not as yet been introduced to the Senate, and probably will not get any farther

OPTOMETRY

Assembly Introductory No 499 makes it illegal for optometrists to advertise in violation of rules to be promulgated by the Board of Regents

HABIT FORMING DRUGS

Assembly Introductory No 557—concurrent Senate Introductory No 357—is the Habit Forming Drug bill of last year It is an exact reproduction of the bill as it was revised at the end of the session It met with our approval then and I presume that our attitude should be the same this year The principal opposition to this bill in the past has come from manufactur-

ers of patent medicines, particularly establishments in Norwich and Rochester

DRUG ADDICTS

Assembly Introductory No 558—concurrent Senate Introductory No 391—would license private institutions where drug addicts are admitted This is an exact copy of a bill introduced last year by Mr Weinfeld His bill died in committee, and I do not know why Dr Vander Veer approved of the bill and wrote to the committee urging its passage

REGISTRY OF PHARMACIES

Assembly Introductory No 594 would amend the pharmacy law, providing that pharmacies, drug stores or other stores having a license or permit to sell or dispose of intoxicating liquors shall not be registered in the manner prescribed by law for the registering of pharmacies, but does not prohibit the lawful possession, sale and

medical study the *preliminary* general education required by the rules of the regents [preliminary to receiving the degree of bachelor or doctor of medicine in this state], *except where the application is for a license to practice osteopathy, in which case he must have had the general education required by the rules of the regents preliminary to receiving the degree of doctor of osteopathy,*

4 Had studied medicine not less than four school years, including four satisfactory courses of at least eight months each in four different calendar years in a medical school registered as maintaining at the time a standard satisfactory to the regents. In lieu of the first two years of such medical course, the regents may accept evidence of graduation with the degree of bachelor or doctor of dental surgery from a registered dental school in which the requirements for admission were the same as those prescribed for a registered medical school, and in which the course of instruction included all of the minimum requirement prescribed for the first two years of the course in a registered medical school. New York medical schools and New York medical students shall not be discriminated against by the registration of any school out of the state whose minimum graduation standard is less than that fixed by statute for New York medical schools. The regents may, in their discretion, accept as the equivalent for any part of the third and fourth requirements, evidence of five or more years' reputable practice, provided that such substitution be specified in the license, and, as the equivalent of the first year of the fourth requirements, evidence of graduation from a registered college course, provided that such college course shall have included not less than the minimum requirements prescribed by the regents for such admission to advanced standing. The regents may also in their discretion admit conditionally to the examination in anatomy, physiology and chemistry, applicants nineteen years of age, certified as having studied medicine not less than two years, including two satisfactory courses of at least eight months each, in two different calendar years, in a medical school registered as maintaining at the time a standard satisfactory to the regents, provided that such applicants meet the second and third requirements of this section (),

5 Has (either) received the degree of bachelor or doctor of medicine from some (registered) medical school in this country or Canada, *registered as maintaining at the time a standard satisfactory to the regents* or (the) a medical degree (of doctor of medicine) from a medical school in a foreign country maintaining a standard not lower than that prescribed for medical schools in this state or a license to practice medicine in a foreign country issued under requirements not lower than those exacted for a medical license in this state unless admitted conditionally to the examinations as specified above

The degree of bachelor or doctor of medicine shall not be conferred in this state before the candidate has filed with the institution conferring it the certificate of the regents that before beginning the first annual medical course counted toward the degree, he had earned a medical student qualifying certificate in accordance with the rules of the regents [the minimum requirement for which, for matriculates after January first, nineteen hundred and seventeen, shall be the successful completion of an approved four-year high school course or its equivalent]

6 Where the application be for a license to practice osteopathy, the applicant shall produce evidence that before nineteen hundred and ten he has studied osteopathy not less than three years, including three satisfactory courses of not less than nine months each in three different calendar years in a college of osteopathy maintaining at the time a standard satisfactory to the regents. [After] or that after nineteen hundred and ten [the applicant for a license to practice under this article shall produce evidence that] he has studied not less than four years including four satisfactory courses of not less than eight months each in four different calendar years in a college maintaining at the time a standard satisfactory to the regents

Section 4 Section one hundred and sixty-seven of such chapter as amended by Chapter four hundred and ninety-six of the laws of nineteen hundred and twenty-three is hereby amended to read as follows

Section 167 Questions The board shall submit to the regents, as requested, lists of suitable questions for thorough examination in anatomy, physiology, hygiene, chemistry, surgery, obstetrics, gynecology, pathology (including) bacteriology, and (diagnosis) *diagnosis*. From these lists the regents shall prepare question papers for all these subjects, which at any examination shall be the same for all candidates, except that the examination may be divided as provided in section one hundred and sixty-six

Section 5 Section one hundred and sixty-nine of such Chapter as last amended by Chapter two hundred and eighty-two of the laws of nineteen hundred and twenty-four is amended to read as follows

Section 169 Licenses On receiving from the state board an official report that an applicant has successfully passed the examinations and is recommended for license, the regents shall issue to him a license to practice according to the qualifications of the applicant. Every license shall be issued by the university under seal and shall be signed by the president and secretary of the board and by the officer of the university who approved the credential which admitted the candidate to examination and shall state that the licensee has given satisfactory evidence of fitness as to age, character, preliminary and medical

THREE BILLS ON THE DISPOSAL OF TUBERCULOUS ANIMALS

Assembly Introductory No 72 would amend the Farms and Markets Law providing against the removal or slaughter of animals known to be infected with tuberculosis, except under the supervision of the Commissioner of Farms and Markets

Assembly Introductory No 73 offers an amendment to the Penal Law making it a felony for any person to sell knowingly, except under the supervision of the Commissioner of Farms and Markets, any bovine animal in which tuberculosis shall have been indicated as a result of the tuberlin test

Assembly Introductory No 681 would amend section 81, Farms and Markets Law, by providing tubercular animals shall not be removed from premises where examined, except for slaughter within county where owner resides, under proper supervision

BACTERIAL COUNTS OF MILK

Assembly Introductory No 76 would amend the Farms and Markets Law, providing that all persons making bacterial counts of milk and cream must be licensed by the Commissioner of Farms and Markets. The license shall be obtained by examination and may extend for five years before renewal

THE NEW PRACTICE OF MEDICINE ACT

Int 955

IN ASSEMBLY,

February 16, 1926

Introduced by Mr Loomis—read once and referred to the Committee on Public Health

AN ACT*

To amend the public health law, in relation to the practice of medicine

The People of the State of New York, represented in Senate and Assembly do enact as follows

Section 1 Section one hundred and sixty-one of chapter forty-nine of the laws of nineteen hundred and nine, entitled, "An act in relation to the public health, constituting chapter forty-five of the consolidated laws," as amended by Chapter three hundred and nineteen of the laws of nineteen hundred and fourteen, is hereby amended to read as follows

Section 161 QUALIFICATIONS No person shall practice medicine unless registered and legally authorized prior to September first, eighteen hundred and ninety-one, or unless licenced by the regents and registered under article eight of chapter six hundred and sixty-one of the laws of eighteen hundred and ninety-three and acts amendatory thereto, or unless licensed by the regents and registered as required by this article, nor shall any person practice under this article who has ever been convicted of a felony by any court, or whose authority to practice is suspended or revoked by the regents (on recommendation of the state board). The conviction of a felony shall include the conviction of any offense which if committed within the State of New York would constitute a felony under the laws thereof. If a person convicted of a felony is subsequently pardoned by the governor of the state where such conviction was had, or by the President of the United States, the regents, may, in their discretion, on application of such person, and on the submission to them of satisfactory evidence, restore to such person the right to practice medicine in this state, unless such conviction has been for misconduct in his professional capacity

Section 2 Section one hundred and sixty-four

of such Chapter is hereby amended to read as follows

(Section 164 EXPENSES The fees derived from the operation of this article shall be paid into the state treasury, and the legislature shall annually appropriate therefrom for the education department an amount sufficient to pay all proper expenses incurred pursuant to this article)

Section 164 EXPENSES Notwithstanding the provisions of any other general, local or special law, all fees, fines, penalties and other moneys derived from the operation of this article shall be paid to the regents of the university and shall be available, together with the appropriations made from time to time by the legislature, for the payment of all proper expenses of the board, including the salaries of the secretary of the board of medical examiners and his assistants, inspectors, examiners, any deputy attorney-general assigned for the purpose of enforcing the provisions of this article, and other employees, and their necessary disbursements including the disbursement on bills duly rendered and audited for the administration of the committee on grievances. The unexpended balance of all such fees, fines, penalties and other moneys derived from the operation of this article remaining on December thirty-first of each year shall be paid into the state treasury

Section 3 Section one hundred and sixty-six of such chapter as last amended by Chapter two hundred and eighty-two of the laws of nineteen hundred and twenty-four is hereby amended to read as follows

Section 166 Admission to Examination The regents shall admit to examination any candidate who pays a fee of twenty-five dollars and submits evidence, verified by oath, and satisfactory to the regents, that he

1 Is more than twenty-one years of age and a citizen of the United States or has declared his intention of becoming such citizen (),

2 Is of good moral character (),

3 Had prior to beginning the first year of

of medicine, or annul his registration, or do both, in any of the following cases

(a) A practitioner of medicine who is guilty of any fraud or deceit in his practice, or who is guilty of a crime or misdemeanor, or who is guilty of any fraud or deceit by which he was admitted to practice, or

(b) Is an habitual drunkard or habitually addicted to the use of morphine, opium, cocaine, or other drugs having a similar effect, or

(c) Who undertakes or engages in any manner or by any ways or means whatsoever to procure or perform any criminal abortion as the same is defined by Section eighty of the penal law or

(d) Who offers or undertakes by any manner or means to violate any of the provisions of Section eleven hundred and forty-two of the penal law

Proceedings for revocation of a license or the annulment of registration shall be begun by filing a written charge or charges against the accused. These charges may be preferred by any person or corporation, or the regents may on their own motion direct the executive officer of the board of regents to prefer said charges. Said charges shall be filed with the executive officer of the board of regents, and a copy thereof filed with the secretary of the board of medical examiners. The board of medical examiners, when charges are preferred, shall designate three of their number as a committee to hear and determine said charges. A time and place for the hearing of said charges shall be fixed by said committee as soon as convenient, and a copy of the charges, together with a notice of the time and place when they will be heard and determined, shall be served upon the accused or his counsel at least ten days before the date actually fixed for said hearing. Where personal service or service upon counsel cannot be effected, and such fact is certified on oath by any person duly authorized to make legal service, the regents shall cause to be published for at least seven times, for at least twenty days prior to the hearing, in two daily papers in the county in which the physician was last known to practice, a notice to the effect that at a definite time and place a hearing will be had for the purpose of hearing charges against the physician upon an application to revoke his license. At said hearing the accused shall have the right to cross-examine the witnesses against him and to produce witnesses in his defense, and to appear personally or by counsel. The said committee shall make a written report of its findings and recommendations, to be signed by all members, and the same shall be forthwith transmitted to the executive officer of the board of regents. If the said committee shall unanimously find that said charges, or any of them, are sustained, and shall unanimously recommend that the license of the accused be revoked or his

registration be annulled, the regents may thereupon in their discretion revoke said license or annul said registration, or do both. If the regents shall annul (such) a physician's registration or revoke his license they shall forthwith transmit to the clerk of the county or counties in which said (accused) physician is registered (as a physician) a certificate under their seal, certifying that such registration has been annulled or license revoked, and said clerk shall, upon receipt of said certificate, file the same and forthwith mark said registration "annulled." Any person who shall practice medicine after his registration has been marked "annulled" shall be deemed to have practiced medicine without registration. Where the license of any person has been revoked, or his registration has been annulled, as herein provided, the regents may after the expiration of one year, entertain an application for a new license in a like manner as original applications for licenses are entertained, and upon such new application they may, in their discretion, exempt the applicant from the necessity of undergoing any examination.

2 Every person now lawfully engaged in the practice of medicine within the state and every person hereafter duly authorized to practice medicine, shall, on or before January first of each year, apply to the secretary of the board of medical examiners for a certificate of registration with the regents of the university upon a blank form which shall be furnished by said secretary and shall pay at such time to said secretary a fee of two dollars.

3 A physician in making his first registration hereunder shall write or cause to be written upon the application blank so furnished by said secretary his full name, post office and residence address, the date and number of his license and such other facts for the identification of the applicant as a licensed practitioner of medicine as the regents may deem necessary and shall duly execute and verify the same before an officer empowered to take acknowledgments of deeds and deliver the same to said secretary by mail or in person. Subsequent registrations after the first registration need not be upon a sworn application by the applicant unless in a particular case the regents, for reasons satisfactory to them, may require that the application be under oath. The secretary of the board may employ and use in obtaining such subsequent registrations the assistance of the secretaries of duly incorporated medical societies who shall be empowered as representatives of the secretary of the board to receive and transmit such application blanks from physicians after the physicians' first registration, together with the license fees payable upon such application.

4 The secretary of the board, on or before October first of each year, after the first registration, shall mail or cause to be mailed to every registered physician a blank form of application.

education and all other matters required by law, and that after full examination he has been found properly qualified to practice [Applicants examined and licensed in accordance with the provisions of this act] There shall be issued to applicants who, when admitted to the licensing examination, were citizens of a foreign country, and who had declared intention of becoming citizens of the United States, [shall] upon passing the examination, [be issued] a license [valid for six years from the date of such declaration of intention and] but upon failure of such licensee within six years from the date of such declaration of intention to furnish evidence of his having actually become a citizen his license shall terminate [become invalid and automatically become revoked] and his registration shall be annulled Applicants examined and licensed by other state examining boards registered by the regents as maintaining standards not lower than those provided by this article and applicants who matriculated in a New York State medical school before June fifth, eighteen hundred and ninety, and who received the degree of doctor of medicine from a registered medical school before August first, eighteen hundred and ninety-five, may without further examination, on payment of twenty-five dollars to the regents and on submitting such evidence as they may require, receive from them an indorsement of their licenses or diplomas conferring all rights and privileges of a regents' license issued after examination The commissioner of education may in his discretion on the approval of the board of regents indorse a license or diploma of a physician from another state, *or country*, provided the applicant has met all the preliminary and professional qualifications required for earning a license on examination in this state, has been in reputable practice for a period of ten years, and has reached a position of conceded eminence and authority in his profession Any physician, who was actually engaged in the practice of medicine in this state prior to September first, eighteen hundred and ninety-one, and who failed to register, although eligible to do so at the time, or any physician whose registration is not legal because of some error, misunderstanding or unintentional omission, may on the unanimous recommendation of the state board of medical examiners that he has submitted satisfactory proof of having complied with all the requirements prescribed by law at the time of his failure to register, or his incomplete registration, receive from the regents under seal a certificate of the facts which may be registered *in accordance with this act* (by any county clerk and shall make valid his registration) Before any license is issued it shall be numbered and recorded in a book kept in the regents' office, and its number shall be noted in the license, and a photograph of the licensee filed with the records This record shall be opened to public inspection and in all

legal proceedings shall have the same weight as evidence that is given to a record of conveyance of land

Section 6 Section one hundred and seventy of such chapter is hereby amended to read as follows

Section 170 Registration (Registry, revocation of license, annulment of registry)
 1 Every license to practice medicine shall, before the licensee begins practice thereunder, be registered in a book kept in the clerk's office of the county where such practice is to be carried on, with name, residence, place and date of birth, and source, number and date of his license to practice Before registering, each licensee shall file, to be kept in a bound volume in a county clerk's office, an affidavit of the above facts, and also that he is the person named in such license and had, before receiving the same, complied with all the requirements as to attendance, terms and amount of study and examinations required by law and the rules of the university as preliminary to the conferment thereof, that no money was paid for such license, except the regular fees paid by all applicants therefor, that no fraud, misrepresentation or mistake in any material regard was employed by any one or occurred in order that such license should be conferred Every license, or if lost, a copy thereof legally certified so as to be admissible as evidence, or a duly attested transcript of the record of its conferment, shall, before registering, be exhibited to the county clerk, who, only in case it was issued or indorsed as a license under seal by the regents, shall indorse or stamp on it the date and his name, preceded by the words, "registered as authority to practice medicine in the clerk's office of _____ county" The clerk shall thereupon give to every physician so registered a transcript of the entries in the register with a certificate, under seal, that he has filed the prescribed affidavit The licensee shall pay to the county clerk a total fee of one dollar for registration, affidavit and certificate The regents shall have power at any and all times to inquire into the identity of any person claiming to be a licensed or registered physician, and, after due service of notice in writing, require him to make reasonable proof, satisfactory to them, that he is the person licensed to practice medicine under the license by virtue of which he claims the privilege of this article When the regents find that a person claiming to be a physician, licensed under this article, is not in fact the person to whom the license was issued, they shall record [reduce] their decision in [findings to] writing and file them in the office of the clerk of the county in which said person resides or practices medicine Said [certificate] decision shall be prima facie evidence that the person mentioned therein is falsely impersonating a practitioner or a former practitioner of a like or different name (The regents may revoke the license of a practitioner

tutes, or (2) the practice of medicine in a legally incorporated hospital by a duly appointed member of the resident staff or by an interne while actually serving in a state hospital or other state institution in which medical service is provided, or (3) the practice of medicine by any physician duly licensed to practice medicine in a neighboring state, who resides near a border of such neighboring state, whose practice extends into this state and who does not open an office or appoint a place to meet patients or receive calls within this state; or (4) any lawfully qualified physician in other states or countries meeting legally registered physicians in this state in consultation, or (5) the furnishing of medical assistance in case of emergency, or (6) the domestic administration of family remedies, or (7) the practice of chiropody, dentistry, veterinary medicine or optometry, provided those practicing are legally authorized and licensed under the laws of this state so to do, or (8) the practice of religious tenets of any church, or (9) the selling of lenses, artificial eyes, limbs or other apparatus or appliances by any person or manufacturer of the same

2 This article shall be construed to repeal all acts or parts of acts authorizing conferment of any degree in medicine causa honoris or ad eundem or otherwise than on students duly graduated after satisfactory completion of a medical course not less than that required by this article as a condition of license

[It is further provided that any person who shall be actively engaged in the practice of osteopathy in the State of New York on the thirteenth day of May, nineteen hundred and seven, and who shall present to the board of regents satisfactory evidence that he is a graduate in good standing of a regularly conducted school or college of osteopathy within the United States which at the time of his or her graduation required a course of study of two years or longer, including the subjects of anatomy, physiology, pathology, hygiene, chemistry, obstetrics, diagnosis, and the theory and practice of osteopathy, with actual attendance of not less than twenty months, which facts shall be shown by his or her diploma and affidavit, shall upon application and payment of ten dollars be granted, without examination, a license to practice osteopathy, provided application for such license be made within six months after the thirteenth day of May, nineteen hundred and seven.] A license to practice osteopathy shall not permit the holder thereof to administer drugs or perform surgery with the use of instruments. Licenses to practice osteopathy shall be registered in accordance with the provisions of this article, and the word osteopath be included in such registration, and such license shall entitle the holder thereof to the use of the degree D O , or doctor of osteopathy

Section 9 Section one hundred and seventy-four of such chapter is hereby amended to read as follows

[174 (Penalties and their collection) Any person who, not being then lawfully authorized to practice medicine within this state and so registered according to law, shall practice medicine within this state without lawful registration or in violation of any provision of this article, and any person who shall buy, sell or fraudulently obtain any medical diploma, license, record or registration, or who shall aid or abet such buying, selling or fraudulently obtaining, or who shall practice medicine under cover of any medical diploma, license, record or registration illegally obtained, or signed, or issued unlawfully or under fraudulent representations or mistake of fact in a material regard, or who, after conviction of a felony, shall attempt to practice medicine, or shall so practice, and any person who shall in connection with his name use any designation tending to imply or designate him as a practitioner of medicine within the meaning of this article without having registered in accordance therewith, or any person who shall practice medicine or advertise to practice medicine under a name other than his own, or any person not a registered physician who shall advertise to practice medicine, shall be guilty of a misdemeanor. Any person who shall practice medicine under a false or assumed name, or who shall falsely personate another practitioner or former practitioner of a like or different name, shall be guilty of a felony. When any prosecution under this article, or under sections eleven hundred and forty-two, eighty, eighty-one, eighty-two, seven hundred and forty-seven of the penal law and any amendments thereto, is made on the complaint of any incorporated medical society of the state, or any county medical society entitled to representation in a state society, any fines collected shall be paid to the society making the complaint, and any excess of the amount of fines so paid over the expense incurred by the said society in enforcing the medical laws of this state shall be paid at the end of the year to the county treasurer.]

174 Penalties

1 Any person who shall

(a) Sell or fraudulently obtain or furnish any medical or osteopathic diploma, license, record, or registration, or aid or abet in the same, or

(b) Practice medicine under cover of any diploma, license, record or registration illegally or fraudulently obtained or signed or issued unlawfully or under fraudulent representation or mistake of fact in a material regard, or

(c) Advertise to practice medicine under a name other than his own or under a false or assumed name, and

2 Any person who not being then lawfully licensed and authorized to practice medicine within this state shall

(a) Practice or advertise to practice medicine, or

(b) Use in connection with his name any de-

for registration addressed to the last known post-office address of such physician or may cause such blank form of application to be sent to such physicians through the secretary of any duly incorporated medical society. The form of application shall be such as to contain proper spaces for the insertion by the applicant of the information required under paragraph two of this section.

5 The secretary of the board shall issue to any duly licensed physician in this state, upon his application therefor in accordance with the provisions hereof, a certificate of registration under seal of the university for the year ensuing and ending December thirty-first.

Upon the first of March in each year, or within ten days thereafter, the secretary of the board shall publish and cause to be mailed to each physician registered hereunder in this state a printed list of the duly registered physicians in this state, and each such published list shall contain at the beginning thereof these words:

"Each registered physician receiving this list is requested to report to the secretary of the board and to the secretary of any duly incorporated county medical society existing in the county of his residence or to the secretary of any incorporated state medical society in which said county medical society is represented, the name and address of any person known to be practicing medicine whose name does not appear in this registry. The names of persons giving such information will not be divulged."

The names of physicians which shall in any year be added to said list after the same shall have been so printed and distributed as aforesaid, shall be reported quarterly on request to the secretary of any duly incorporated state medical society of which county medical societies are components.

6 Any licensed physician who fails or neglects to register by January first of any year as required by the provisions of this section shall be required to pay for registration, in addition to the fee of two dollars, a further fee of one dollar for each thirty days or part thereof that he is in default, and any licensed physician who wilfully refuses or omits to register hereunder and engages in practice shall be subject to a civil penalty of one dollar for each day that such practice shall continue, and if the same continues for more than thirty days the penalty thereafter shall be five dollars per day so long as the said practice shall continue, said penalty shall be recoverable in an action by the attorney-general of the state maintained in the name of the people of the State of New York.

7 The penalties provided in this section for failure, neglect or omission of a duly licensed physician to register under this article shall be the only penalties that may be imposed therefor, and the legality of his license shall not be affected

thereby, and such penalties may for good cause shown, in the discretion of the regents, be remitted or compromised.

8 Each licensed physician shall conspicuously display his proper registration certificate in his office at all times.

Section 7 Section one hundred and seventy-one of such chapter, as amended by chapter fifty-three of the laws of nineteen hundred and fifteen, is hereby repealed.

Section 8 Section one hundred and seventy-three of such chapter as last amended by Chapter two hundred and eighty-two of the laws of nineteen hundred twenty-four is hereby amended to read as follows:

(173) Construction of this Article. (This article shall not be construed to affect commissioned medical officers serving in the United States army, navy or marine hospital service while so commissioned, or any one while actually serving on the resident medical staff of any legally incorporated hospital, or any one while actually serving as an interne in a state hospital or other state institution in which medical service is provided, or any legally registered dentist exclusively engaged in practicing dentistry, or any person or manufacturer who mechanically fits or sells lenses, artificial eyes, limbs, or other apparatus or appliances, or is engaged in the mechanical examination of eyes for the purpose of constructing or adjusting spectacles, eyeglasses and lenses, or any lawfully qualified physician in other states or countries meeting legally registered physicians in this state in consultation, or any physician residing on a border of a neighboring state and duly licensed under the laws thereof to practice medicine therein, whose practice extends into this state and who does not open an office or appoint a place to meet patients or receive calls within this state, or any physician duly registered in one county called to attend isolated cases in another county, but not residing or habitually practicing therein, or the furnishing of medical assistance in case of emergency, or the domestic administration of family remedies, or the practice of chiropody or the practice of the religious tenets of any church. This article shall be construed to repeal all acts or parts of acts authorizing conformant of any degree in medicine *causa honoris* or *ad eundem* or otherwise than on students duly graduated after satisfactory completion of a preliminary medical course, nor less than required by this article as a condition of license.)

1 This article shall not be construed to prevent the following: (1) The practice of medicine in this state in obedience with the requirements of the laws of the United States of any commissioned medical officer serving in the United States army, navy, or public health service while engaged in the performance of the actual duties prescribed for him under the United States sta-

(d) That a physician is guilty of untrue, fraudulent, misleading or deceptive advertising, or advertising that he can cure or treat disease by a secret method, procedure, treatment or medicine, or that he can treat operate and prescribe for any human condition by a method, means or procedure which he refuses to divulge upon demand to the committee on grievances, or

(e) That a physician did undertake or engage in any manner or by any ways or means whatsoever to procure or to perform any criminal abortion and or to violate section eleven hundred and forty-two of the penal law

Section 11 Such chapter is hereby amended by adding thereto a new section to be section one hundred and seventy-four-b, to read as follows

174b Procedure in Disciplinary Proceedings Within sixty days after this act shall take effect there shall be appointed in accordance with the provisions hereof a committee which shall be known as the committee on grievances, which shall consist of ten members who shall be appointed by the regents in accordance with the provisions thereof

1 The term of office of each of said members of said committee shall be five years, except that upon the taking effect of this act two members shall be appointed whose terms shall expire December thirty-first, nineteen hundred and twenty-seven two members whose terms shall expire December thirty-first, nineteen hundred and twenty-eight, two members whose terms shall expire December thirty-first, nineteen hundred and twenty-nine, two members whose terms shall expire December thirty-first, nineteen hundred and thirty, and two members whose terms shall expire December thirty-first, nineteen hundred and thirty-one, and as such terms expire they shall be filled by the addition to said committee of two members whose terms shall be five years from the expiration of the terms of their predecessors In the case of a vacancy at any time, by resignation, death or otherwise in the membership of the committee, the said vacancy shall be filled for the unexpired term in the same manner as provided for in the original selection of such member

2 Any duly incorporated state medical or osteopathic society having two hundred or more members may nominate candidates for members of such committee, not to exceed three nominations for each member of such committee to which such society shall be entitled hereunder When the candidates are so nominated, the regents shall appoint for the terms specified herein as they shall determine, said members of the said committee, so that said committee shall consist of four members who have been duly nominated by the medical society of the State of New York, two members by the New York State Homeopathic Society one member by the New

York State Osteopathic Society, and the regents, upon their own nomination, shall appoint three members of conspicuous professional standing Each member of the said committee shall be a duly licensed physician of this state

3 The members of said committee shall serve without a compensation and shall annually, within ten days after the first day of January of each year, organize by the election of a chairman and a secretary

4 The members of said committee shall have jurisdiction to hear all charges against duly licensed physicians of this state for violation of the provisions of section one hundred and seventy-four hereof, except subdivision 2, clause (b), and upon such hearing the said committee shall determine the said charges upon their merits, and the regents shall, after due notice and hearing, upon the receipt from said committee of the record, findings and determination of said committee wherein and whereby such practitioner has been found guilty, in their discretion revoke and annul his license, annul his registration, suspend him from practice, or reprimand or otherwise discipline him. Proceedings against any practitioner under this section shall be begun by filing a written charge or charges against the accused These charges may be preferred by any person, corporation or public officer, and they shall be filed with the secretary of the committee on grievances, and said secretary shall forward to the executive officer of the regents a copy of such charges in all cases in which said committee shall deem a trial necessary The chairman of said committee, when charges are preferred may designate one or more of the members of said committee, including at least one member who represents the same school of practice as the physician against whom the charges are preferred, to hear and report upon said charges to said committee The time and place of the hearing of such charges shall be fixed by the secretary of the committee as soon as convenient and a copy of the charges, together with a notice of the time and place when they will be heard shall be served upon the accused or his counsel at least ten days before the date actually fixed for said hearing Where personal service or service upon counsel after due diligence cannot be effected and such fact is certified on oath by any person duly authorized to make legal service, the secretary of the said committee shall cause to be published for four times, at least thirty days prior to the hearing, a notice of the hearing in a newspaper published in the county in which the physician was last known to practice, and a copy of such notice shall also be mailed to the accused at his last known address All such notices of hearing of charges shall contain a plain and concise statement of the material facts without unnecessary repetition, but not the evidence by which the charges are to be proved with a notification that a stenographic record of

signation tending to imply or designate him as a practitioner of medicine, or

(c) Use the title "doctor" or any abbreviation thereof in connection with his name or with any trade name in the conduct of any occupation or profession involving or pertaining to the public health or the diagnosis or treatment of any human disease, pain, injury, deformity or physical condition unless duly authorized by law to use the same, and

3 Any person who during the time his license to practice medicine shall be suspended or revoked, or who shall be convicted of a felony shall practice medicine, shall be guilty of a misdemeanor

Such misdemeanor shall be punishable by imprisonment for not more than one year or by a fine of not more than five hundred dollars, or by both such fine and imprisonment for each separate violation and for a second offense shall be punishable by both such fine and imprisonment

4 All courts of special sessions within their respective territorial jurisdictions are hereby empowered to hear, try and determine such crimes without indictment and to impose in full the punishments or fines and imprisonments herein prescribed

Such misdemeanors shall be prosecuted by the attorney-general in the name of the people of the state, provided, however, that nothing in this section shall be interpreted to prevent or impede the prosecution of such proceedings by the district attorney of any county having a population of five hundred thousand or more, when such proceedings shall have been initiated by him

5 The display by any person of a sign or an advertisement bearing a name as a practitioner of medicine in any manner or by implication or containing any other matter forbidden by law shall be presumptive evidence in any prosecution or hearing of a holding out and of the practice of medicine by such person for each separate day such sign or advertisement is anywhere displayed by anyone, but such presumptions are rebuttable by the defense It shall be necessary to prove in any prosecution or hearing under this article only a single act prohibited by law or a single holding out or an attempt without proving a general course of conduct, in order to constitute a violation

6 In any action for damages for personal injuries or death against a person not licensed hereunder for any act or acts constituting the practice of medicine as herein defined, when such act or acts were a competent producing proximate or contributing cause of such injuries or death, the fact that such person practiced medicine as herein defined without being duly licensed shall be deemed prima facie evidence of negligence

7 All violations of this act, when reported to the regents and duly substantiated by affidavits

or other satisfactory evidence, shall be investigated, and if the report is found to be true and the complaint substantiated, the regents shall report such violation to the attorney-general and request prompt prosecution of such violation The regents may appoint not less than five or more than seven inspectors, to be paid as provided in section 164 of this article under the direction of the secretary of the board of medical examiners, to investigate promptly and thoroughly such violations and to procure where possible legal evidence of the same for prosecution of the offenders Upon the application of the committee on grievances to the secretary of the board of medical examiners, the services of an inspector or inspectors may be furnished for making necessary investigations for said committee

In the prosecution of any criminal action for violation of this article by the attorney-general or his deputy, said attorney-general or his deputy shall exercise all the powers and perform all the duties with respect to such actions or proceedings which the district attorney would otherwise be authorized or required to exercise or perform, and in such actions or proceedings the district attorney shall only exercise such powers and perform such duties as are required of him by the attorney-general or the deputy attorney-general so attending

Section 10 This chapter is hereby amended by adding thereto a new section to be section one hundred and seventy-four-a to read as follows

174a A Revocation of Certificates, Annulment of Registrations

1 Whenever any practitioner of medicine shall be convicted of a felony the registration of the person so convicted shall be annulled and his license revoked by the regents It shall be the duty of the clerk of the court wherein such conviction takes place to transmit a certificate of such conviction to the regents Upon reversal of such judgment by a court having jurisdiction, the regents, upon receipt of a certified copy of such judgment or order of reversal, shall vacate their order of revocation or annulment

2 The license or registration of a practitioner of medicine may be revoked, suspended or annulled or such practitioner reprimanded or disciplined in accordance with the provisions and procedure of this act upon decision after due hearing in any of the following cases

(a) That the physician is guilty of fraud or deceit in the practice of medicine or in his admission to the practice of medicine,

(b) That a physician has been convicted in a court of competent jurisdiction, either within or without this state of a crime or misdemeanor or

(c) That a physician is an habitual drunkard or addicted to the use of morphine, cocaine or other drugs having similar effect, or has become insane—or

NEWS NOTES

BRONX COUNTY SOCIETY

A regular meeting of the Bronx County Medical Society, held at Concourse Plaza, on January 20, 1926, was called to order at 9 p. m., the retiring President, Dr. Jacobs, in the Chair.

Dr. Jacobs presented Dr. Edward R. Cuniffe, who thereupon took the Chair and addressed the Society as follows:

"The preceding Administration was not only notable for the high standard of its scientific programs, but it gave us many progressive measures. The first of these inherited activities I would mention is the Public Health Program. This program will be further developed, and demonstrations of Periodic Health Examination methods will be given before the members of the Society. The post-graduate medical plans for education are now under way, and the system will be inaugurated during the coming year. Not alone lectures will be given, but also tentative plans have been made for the instruction of members in different methods of practice in the use of special instruments at the various hospitals in this County. This program will be submitted to you for your approval in the very near future. The programs will be elastic enough to be changed sufficiently often to give the most assistance to the greatest number.

"During the past year a Building Committee was appointed to ascertain the sentiments of the Society toward owning and maintaining its own Home. We look forward to great progress in this matter. Much remains to be done as to the method of the issuing of bonds, arrangement for their payment, selection of site type and size of building, and final decision in regard to undertaking the task alone or in conjunction with other allied professions.

"The legislative program of our Society has grown to great importance, and now that a Municipal Legislature for the practice of Home Rule in the making of plans affecting this city has been established, it gives cause for increased activity in this direction. This Municipal Legislature will have to do with passing laws which govern our municipal hospitals, which is a very important item.

"The matter of most importance before us is the proposed Medical Practice Act. The February meeting of our Society will be an Economic meeting and this Bill will be discussed at that time.

"Some attempt has been made to stabilize the programs for the Stated Meetings of the Society, having papers and discussions on certain sub-

jects rotating in a regular fixed manner, and the following tentative outline has been arranged. The January meeting will be given over to a medical topic, the meeting in February will be an Economic one, March meeting devoted to Surgery, April, Pediatrics, May, Obstetrics, June, a Clinical Meeting, October, Medical Jurisprudence, November, Gynecology or Neurology. This program can be changed somewhat as necessity demands and is to be supplemented by the lectures, demonstrations and conferences of the Post-Graduate Education work.

"I would call the attention of the members to the next meeting of the House of Delegates of the Medical Society of the State of New York, to be held, under the auspices of our Society, beginning March 29th. For the first time in the history of the Bronx, we have one of our members occupying the office of the President of the Medical Society of the State of New York, and it behooves us all to enter into the spirit of this in order to make the meeting a success.

"I would suggest that either a Committee be appointed, through an Amendment to our By-Laws for a Press Reference Committee, or that the Chair be empowered to designate one of the existing Committees, to which all newspaper men could be referred. Any article appearing in the public press which needed reply could be answered by this Committee. The Committee could take care of the publication of worthy news without the use of any names, and any newspaper articles published by clubs could be handled by the same Committee if deemed advisable."

Following new members were elected: Drs. William Aronson, Pauline Harden Barnache, Louis Kirschenbaum, Henry J. Koustas, Joseph Lubart, Abraham Mahler, and Nathan Schwartz.

A resolution was adopted regarding the death of Dr. Frank H. Zitz.

It was moved and carried that the Bulletin Committee be designated as a Press Reference Committee, to which all matters of newspaper publicity be referred.

SCIENTIFIC PROGRAM

Incipient Valvular Endocarditis as a Clinical Concept, Nicholas Lukin, M.D.

Certain Considerations of Heart Disease from the Standpoint of Cause, John Wyckoff, M.D.

such proceedings will be kept, and that the accused will have opportunity to appear either personally or by counsel at the hearing, with the right to produce witnesses and evidence upon his own behalf, to cross-examine such witnesses, to examine such evidence as may be produced against him, and to have subpoenas issued by the said committee. Said committee to whom said charges were referred shall make a written report of findings and recommendations and the same shall be forthwith transmitted to the secretary of the committee on grievances, with a transcript of the evidence. Said committee may thereupon act upon said recommendations as it shall deem fit, or may take further testimony if the same seem desirable in the interest of justice. Thereupon, the said committee shall determine said charges upon their merits, by a majority vote of the members (the vote of each member of said committee to be recorded as part of the committee's findings). If the practitioner is found guilty of such charges, said committee shall transmit to the regents the record, findings and determination wherein and whereby such practitioner has been found guilty, and the regents, after due hearing, shall in their discretion cause to be executed the determination of said committee as herein above provided. If the practitioner is found not guilty, said committee shall order a dismissal of the charges and the exoneration of the accused. Nothing herein contained shall estop the regents from initiatory proceedings in any case.

5 Any licensed practitioner found guilty under the provisions of this section, or whose license is otherwise revoked or suspended, or registration annulled, or who has been refused registration, or who is otherwise reprimanded or disciplined under this article, may have an order of certiorari for the purpose of reviewing such determination returnable before the appellate division of the third judicial department, but no such determination shall be stayed or enjoined, except upon application to such appellate division, after notice to the attorney-general, the committee on grievances or any member thereof may issue subpoenas and administer oaths pursuant to section sixty-one of the public officers' law in connection with any hearing or investigation under this article, and it shall be the duty of such committee to issue subpoenas at the request of and upon behalf of the defense. Said committee on grievances shall not be bound by the laws of evidence in the conduct of its proceedings, but the determination shall be founded upon sufficient legal evidence to sustain the same. The regents shall furnish legal advice and assistance to said committee whenever such service is requested.

6 Any controversy between two or more physicians, or between a physician or physicians and another person, which said parties to such con-

troversy agree to submit to arbitration, may be submitted in writing to said committee on grievances, which may in its discretion act as arbitrator in said controversy, and the decision of said committee upon such arbitration shall be final, and where the same orders the payment of a sum of money, the same may be docketed as a judgment of a court of record and enforced as such judgment, provided the terms of the arbitration include such provision.

7 The regents may remove any member of said committee from office who shall have been found guilty, after due hearing, of malfeasance in office or neglect of duty.

8 No member of the committee shall participate in any way in the hearing and determination of any charges in which he may be either a witness as to facts or an accused, nor in any case where the parties, complainant or accused are related to him by consanguinity or affinity within the sixth degree. The degree shall be ascertained by ascending from the member of the committee to the common ancestor and descending to the party, counting a degree for each person in both lines, including the member of the committee and the party and excluding the common ancestor.

9 Should, for any reason, three or more members of the committee be disqualified from participating in the hearing and decision of any case, or be for other reason unable to participate therein, then places may be temporarily filled for the purpose of determining the case to be heard by the remaining members of the committee nominating twice the number of candidates for such vacancy from whom there shall be selected by the chairman of the committee, after notice to the respective parties, the necessary number of members to constitute a quorum. A quorum of said committee shall consist of six members.

10 Said committee shall have power to make such rules and regulations for the conduct of its business as it shall deem necessary, provided such rules and regulations do not conflict with any of the provisions of this article.

11 The said committee shall have power, where a proceeding has been dismissed, either on the merits or otherwise, to relieve the accused from any possible odium that may attach by reason of the making of charges against him, by such public exoneration as it shall see fit to make if requested by the accused so to do.

Section 12 If any clause, sentence, paragraph or part of this act shall for any reason be adjudged by any court of competent jurisdiction to be invalid, such judgment shall not affect, impair or invalidate the remainder of said act, but shall be confined in its operation to the clause, sentence, paragraph or part thereof directly involved in the controversy in which such judgment shall have been rendered.

Section 13 This act shall take effect immediately.

SCIENTIFIC PROGRAM

Incipient Valvular Endocarditis as a Clinical Concept, Nicholas Lukin, M.D.

Certain Considerations of Heart Disease from the Standpoint of Cause, John Wyckoff, M.D.

MEDICAL SOCIETY OF THE COUNTY OF QUEENS

The regular meeting was held at Eagle Palace, Jamaica, January 26th 1926, President Dennis E. McMahon, M D, in the chair

The scientific session opened with a presentation on

I The Treatment of Pneumonia by Harlow Brooks, M D Dr Brooks brought out the fact that pneumonia is a local disease situated in the lungs, and not a general disease of the body, with relatively few complications No immunity is developed or at best a short lived immunity Many times there is a sensitization The treatment is directed to the patient rather than the disease Emphasis was placed upon rest as the most efficient treatment This had reference to emotional as well as physical rest Details covering the clothing and care of the patient were discussed Objections to cupping and the use of poultices are the disturbance it causes the patient An electric pad or hot water bag meets every requirement The same applies to various other applications The value of rest artificially produced and the relief of suffering by the use of opium usually as morphine was emphasized Emphasis was placed on The support of the circulation, the treatment of the peripheral circulation, the maintenance of proper excretion both of kidneys and bowels, the control of cough by the judicious use of morphine, codeine or heroin and possibly later in the disease by the use of expectorants Also strapping of the chest or abdomen by a band or corset, a diet consisting of sweetened fruit juices and the proper use of alcohol, the importance of treatment of tympanitis by irrigation or alkaline laxatives, the relief of respiratory distress including an abundance of fresh air, the nervous management including meningitis and delirium, and finally a consideration of the specific treatments regarding which the speaker valued serum in type I cases, not later than 72 hours, after which there is danger of its adding a serious anaphylactic shock Other specific treatments have thus far proved disappointing

A discussion followed next was participated in by Drs Boettiger, Stein, Whelan, Koumrian, Lehman, Victor and Langer, and was closed by Dr Brooks

II A presentation on Empyema—A review of the closed method of treatment with lantern slide illustrations, by Ralph F Harloe, M D, who emphasized the advantages of the close method of drainage and irrigation and the lessened mortality resulting therefrom He described special instruments for the procedure and exhibited X-rays of patients during the progress of the disease Discussion by Drs Stein, Biffer, and closed by Dr Harloe

III J Paul McHugh, M D, reported a case

of actinomycosis of the lungs Dr Boettiger reported the necropsy

In the business session nine new members were elected and three received by transfer from other societies The report of the Committee on Graduate Education showed a gratifying activity among members of the profession in the county

A course of 14 bi-monthly afternoon lectures on practical subjects is being given and will continue through May, and their messages are being received by large audiences

Special practical courses are being given at the hospitals throughout the County These include

St Johns Hospital

- 1 Heart Disease
- 2 Obstetrics
- 3 Clinical Pathological Conference
- 4 Neurological Diagnosis
- 5 Dermatology
- 6 Medical Ophthalmology

Flushing Hospital

- 1 Surgical Diagnosis and After-Treatment
- 2 Fractures
- 3 Infant Feeding

Jamaica Hospital

- 1 Diabetes
- 2 Clinical Surgery
- 3 Clinical Demonstration of Treatment of Fractures of Extremities Methods of Reduction and Apparatus

Rockaway Beach Hospital

- 1 Diagnosis and Treatment of Ear, Nose and Throat Diseases
- 3 Pediatrics—Nutrition and Common Disorders of Infancy and Childhood
- 4 Clinical Diagnosis

Courses are open to any registered physician

Dr Courten reported a communication regarding the appointment of Committees from the county societies within the limits of the City of New York to form a Joint Committee on Nursing, especially with reference to the educational requirements On the adoption of resolutions the chair appointed Drs T C Chalmers, Carl Boettiger and E E Smith, such a Committee for the County of Queens

The Public Health Committee was instructed to look into the matter of establishing a City Hospital in the County of Queens

THE DAILY PRESS

Stinging comments on the failure of physicians to make effective use of lay periodicals in broadcasting health information are found in an editorial entitled "Good News Suppressed,"* in the January 30th issue of the *Saturday Evening Post*. The article is valuable because it holds a mirror before the medical writer and reveals him to himself as thoughtful laymen see him. As is usual with such articles, the writer mistakes symptoms for pathology, and prescribes remedies which are not absorbable. He assumes that the difficulty lies in the doctors' central broadcasting station, and ignores the possibility that the laymen's receiving sets may be overwhelmed with static and meaningless squawks which completely obscure the doctor's message, or that many laymen may have no receiving sets at all. With this explanation the following extracts from the article are presented:

"The science of medicine is, as far as laymen are concerned, the most tongue-tied of all the learned professions. Clergymen can deliver their messages in words of one syllable to high and low alike. Lawyers, by skill of word and clarity of expression, can make juries of the most limited education comprehend the essentials of highly intricate cases. The doctors alone are the bond-slaves of a vocabulary drawn from the dead languages.

"Our physicians, surgeons and health officers are fairly boiling over with important information which they desire to communicate to the general public, but somehow they lack the simple, racy English in which to get it over, or the sense of form and accent which would make it interesting and attractive. This inability to write plain understandable English so readable in form and so accurate in statement that it is easy to make it accessible to large bodies of readers, is costing thousands upon thousands of American lives every year. Attention is called to this condition because it has a message to Garcia which it is not delivering.

"The physicians, however, despite the best intentions, are contributing far less effectually than they might to the cause of preventive medicine. Their zeal for scientific advancement knows no bounds, but they forget that much of their newly acquired knowledge must remain barren until it has become common property and its significance has been grasped and realized. Even the commonplaces of modern medicine have not been universally taught. Coughs are still neglected, eyes, ears, noses, throats and teeth, which are obviously defective, are allowed to go for years

without proper inspection, lumpy formations are ignored in the vain hope that they will disappear, adenoid growths are tolerated, and millions upon millions of us for lack of expert advice continue habitual diets which are little better than slow poisons. Indigestion, for the most part avoidable, has become our national disease.

Popular medical education cannot be achieved in a day, nor can it be accomplished by scattered outbursts of even the best-trained publicity in many days. The population of the country is too numerous and too widespread, and the handicaps are too formidable to warrant any hope of the sort. Not the least of these handicaps is the attitude of the medical profession toward the lay press. For centuries physicians and surgeons have considered the lay press as common and unclean.

"The enlightened physician has a great body of news of the highest importance to communicate to non-medical readers. He is fully alive to the educative powers of the newspaper and periodical press, but he does not know how to use the mighty engine he has so long despised. He is unable to frame his warnings with such skill that he can have them printed, or having had them published he cannot lure people into reading, digesting and heeding them. His love of long, accurate Greek and Latin words is his he-etting sin, and his punishment is in witnessing the affliction which might have been avoided if he had been able to deliver his message interestingly in simple vernacular English.

"When the medical profession become more fully awake to its responsibilities in this field, it is to be hoped that it will perceive the gravity and importance of its problem and attack it in force over a nation-wide front. Some national body, such as the American Medical Association, which has made such a good start along these lines ought to take up the matter in a big way and work out a comprehensive program which would unify the efforts of the agencies already in the field, and by coöperating with state and local boards of health, hospital clinics, community centers and county medical societies, cover the lay press of the whole country. Local organizations should cultivate their own home papers and see that they are supplied with simply and attractively written reports of all transactions in which the public is immediately concerned. They should spare no pains to make them as readable as the effusions of the sporting editor, who has perhaps reported their meetings in the past and as much more accurate as their technical knowledge will permit. Eminent

* Reprinted by special permission from the *Saturday Evening Post*, copyright 1926 by the Curtis Publishing Company.

specialists should be induced to continue and multiply the excellent health talks which have been broadcast by radio

"The old-time prejudice against medical men writing on medical matters for the lay press should give way to a more enlightened code, and young physicians should be encouraged to take pen in hand with a view to bringing about a closer understanding between doctors and patients. The good which would follow would outweigh the evil

"Any adequate nation-wide program of popular medical education such as is here contemplated would involve heavy outlays both of brains and of money, but its importance and its benefits, both social and economic, would be so stupendous that there is small reason to doubt that if the doctors would supply the brains the business world would find the money, and the newspaper publishers would furnish the white paper. There is no novelty in the basic idea. Many leaders of the medical profession have long had it in the back of their minds, but while it simmers there, it does no good to suffering humanity. The time has come to convert good intentions into action."

If physicians have the power to command good health by means of the spoken or written word, then ministers of the Gospel can convert the world to unselfish service, and lawyers can secure equal rights for all and rouse dullards to take advantage of their opportunities. But the questions arise—Will the people understand the scientific subjects which doctors present? Which do the people want, facts or promises?

It is noteworthy that serious medical topics are not taken as subjects for cartoons or sentimental poems. They do not lend themselves to current methods of publicity, because their comprehension requires study and intensive concentration far beyond that which they would get if they were sandwiched between a jazz dance and a bed-time story.

However, the general indictment of the *Saturday Evening Post* is true. Doctors do not use the lay press as much as they should. To inspire medical publicity for the benefit of the laity is one of the objects of the department of Daily Press in this JOURNAL.

PATHOMETRY

Of the making of new words there is no end, especially medical words. The New York *Herald-Tribune*, February 14th, records a new word—pathometry—coined to represent the measure of illness, or the study of illness from an economic standpoint. What is the prevalence of various diseases? What hospital provision is needed for them? How much working time is lost on account of illness? How much of the illness is preventable? What is the relation of diseases to occupation, age, race, and economic states? Such questions as these are included in the study newly called "pathometry." The study is not new, but has been made ever since the days of health departments and medical journals and libraries. Its newer phase is large economic, and could well have been called by the simple descriptive term of the economics of illness. The American Indians and the Germans would run the descriptive terms together to form a word whose meaning would be evident without a dictionary.

The publishers of the new editions of medical dictionaries go to great pains to advertise the up-to-dateness of their books, and devote whole pages to the enumeration of new words that have been coined since the last editions.

A language is often said to reflect current progress, but is it necessary to coin a new word to stand for every new medical conception? A considerable part of the time of a medical student is spent in learning technical terms, and it would seem that a generation ago there were more terms than were needed, or that a student could use intelligently. The coinage of new words is now going on at a faster rate than ever, and medical writers feel an urge to use them in order to show their progressiveness. Is it not true that they sometimes serve to conceal rather than reveal thought? Medical men often have difficulty in following the thoughts of their confreres who revel in polysyllabic terms that are the despair of stenographers and of ordinary doctors who seek ideas rather than conventional symbols. It is no wonder that the Editor of the *Saturday Evening Post* calls for simplicity in medical language. It would seem that Webster's English Dictionary already contains a sufficient number and variety of words to meet the legitimate needs of doctors.

BOOK REVIEWS

THE NATIONAL HEALTH SERIES To be published in twenty volumes by the Funk & Wagnalls Company, New York, 1924 16mo Average number of pages, 70 Bound in Flexible Fabrikoid Price per set, \$6.00 net, per volume, 30c. net.

The Young Child's Health By Henry L. K. Shaw, M.D. This little volume deals with the hygiene of the child between two and six years of age, the so-called preschool period. The brief chapters on Growth and Development, Health and Hygiene Problems, and Foods and Feeding are particularly commendable.

The Human Machine. How Your Body Functions By William H. Howell, M.D. Dr. Howell has written in language so simple and concise that the layman who reads this book cannot fail to gain some conception of the physiological processes of the body.

Taking Care of Your Heart. By T. Stuart Hart, M.D. Here is a manual which every physician can give to a patient suffering with heart disease. It is filled with good, hard common sense, and the patient who reads it cannot but see the value of sincere co-operation with his physician.

The Quest for Health. By James A. Tobey, M.S. Mr. Tobey has outlined herein those essentials for personal health with which everyone should be familiar. An interesting feature is his discussion of the kind of physician a person should consult. He recommends that graduates of Class A schools only be consulted. We acknowledge that the recent graduates to be recommended must be graduates of such schools, but there are large numbers of older physicians who were graduated from institutions which at that time may have been of the best, but which now are not rated A. These men are put in a very bad light by this rather radical recommendation of the author's.

Food for Health's Sake. By Lucy H. Gillett, M.A. At last we have a volume, brief though it is, dealing with diet and which does not contain a list of foods with their caloric values. Most individuals ingest far more calories than are necessary anyway. This book stresses two points in particular—the importance of the protective foods, and the way to feed a family with economy.

Venereal Diseases By William F. Snow, M.D. Dr. Snow has probably done more than any other one person to advance the campaign for the prevention of syphilis and gonorrhea. This little volume which he presents sums up the whole situation from various standpoints—lay, legal, medical, and moral.

Tuberculosis. Nature, Treatment and Prevention. By Linsly R. Williams, M.D. This volume contains clear, concise, simple statements of the causes, symptoms and treatment of tuberculosis. Although primarily intended for the layman, many physicians will find much of value in what Dr. Williams says.

The Expectant Mother By Robert L. DeNormandie, M.D. The hygiene of pregnancy, labor and puerperium is carefully explained by the author, and the pregnant woman reading this little book will find her fears dispelled.

Love and Marriage. Normal Sex Relations By T. W. Galloway, Ph.D. The only way in which the result of experience regarding love, marriage and sex relations in general can be made of service to the younger generation is by means of education, and the author deals with these subjects in such a sane, unoffensive and scientific manner that many readers should be reached and should profit thereby.

E. H. MARSH

ANAPHYLAXIS AND SENSITISATION With special Fer-
erence to the Skin and Its Diseases. By R. CRANSTON
Low, M.D., F.R.C.P. Lecturer, Diseases of the Skin,
Edinburgh University. 16 colored plates, 7 half-tone
illustrations. William Wood and Co., New York,
1925. Price, \$6.50.

This book is the reproduction of a thesis which was presented for the degree of M.D. of the University of Edinburgh and was awarded a gold medal. The author is an assistant of Sir Norman Walker in the Royal Infirmary at Edinburgh, where the work was carried to completion. The truly splendid colored plates of skin diseases with which this volume is illustrated are reproductions of those used by Walker in his *Introduction to Dermatology*.

No attempt has been made to describe the diseases, nor is treatment suggested, the author has, however, done much to show just how certain diseases of the skin are caused—a long step in the right direction in dermatological teaching. Chapters are devoted to anaphylaxis and sensitization and their relation to serum, sickness, urticaria, syphilis, tuberculosis, fungus and focal infections, drug eruptions, dermatitis venenata, eczema, etc.

Appended to each chapter are the author's conclusions, which are fair and impartial and greatly assist the student. A complete bibliography of the subject occupies the last eighty pages.

The book is well printed, a novelty being the use of bold-face type in printing the names of other authors whose writings are drawn upon. NATHAN T. BEERS

LEPROSY By SIR LEONARD ROGERS, M.D. F.R.C.P., F.R.C.S. (Retired), physician and Lecturer, London School of Tropical Medicine, and ERNEST MUIR, M.D., F.R.C.S., Edin., Research Worker in Leprosy School of Tropical Medicine and Hygiene, Calcutta. Illustrations. Map showing world distribution of Leprosy. William Wood and Co., New York, 1925. Price \$4.75.

This volume includes in amplified form the first three Croonian Lectures for 1924 delivered before the Royal College of Physicians of London by the first-named author. It is divided into six general sections including History and Distribution, Epidemiology and Communicability, Prophylaxis, Etiology, Clinical and Treatment, and is a masterly and exhaustive treatise on the whole subject.

As the Authors state, the Leprosy problem has baffled the profession for over three thousand years in the absence of any curative treatment, and now that effective methods are available of clearing up the symptoms and infectivity of most early, and some more advanced cases, the whole question has entered on a few and more hopeful epoch, and requires reconsideration in the light of our present knowledge.

The chapters on treatment are intensely interesting and are beautifully illustrated by photographs made of the patients themselves before and after treatment by the newer methods, which, of course, are given in full. Both of the authors are medical men of wide experience in this field, having labored for many years in Calcutta.

NATHAN T. BEERS

SYMPTOMS OF VISCERAL DISEASE A Study of the Vegetative Nervous System in Its Relationship to Clinical Medicine By FRANCIS MARION POTTENGER, A M., M.D., LL.D., F.A.C.P. Third Edition. Eighty-six Illustrations, Ten Color Plates. The C. V. Mosby Co., 1925. Price, \$6.50

This book might well be called "The Vegetative Nervous System in Health and Disease." Much of the interesting data on this important subsidiary of the central nervous system is incorporated in the book. The fundamental principles of the physiology of the system are repeated so often under various subheadings that they cannot be missed. The author uses italics freely, which always detracts from the value of a book. The value of the book could be enhanced many fold if the repetitions were removed, and as a consequence the book could be reduced to about 100 pages. The very interesting explanation of many visceral symptoms would thus be more compact, and one would not tire so soon in an endeavor to get to the end of the journey.

J. ARTHUR BUCHANAN

THE INTERNATIONAL MEDICAL ANNUAL A Year Book of Treatment and Practitioner's Index. Forty-third year, 1925. William Wood and Co., New York. Price, \$6.00

The present issue is the forty-third appearance of a year book of medical and surgical treatment, and while it purports to be of an international nature, it is overwhelmingly English in its list of contributors and in the articles reviewed.

Of about thirty collaborators one notes but four Americans, namely, A. W. Adson of Rochester, E. Wyllis Andrews and Edmund Andrews of Chicago, and J. Ramsay Hunt of New York.

Many valuable and interesting articles are reviewed, one which seemed of special attraction was from the *Presse Medicale* describing the use of lipiodol by intratracheal injection for X-ray diagnosis of pulmonary conditions, especially bronchiectasis.

Books of this kind are of particular value to the busy practitioner who has not the time to read all the current literature during the year and who is anxious to keep abreast of the times by having the outstanding writings summarized for him.

The vitally important part of a year book is naturally the index, and in this case it is commendably good.

WM. HENRY DONNELLY

GERIATRICS A TREATISE ON THE PREVENTION AND TREATMENT OF DISEASES OF OLD AGE AND THE CARE OF THE AGED. By MALFORD W. THEWLIS, M.D., Editor Medical Review of Reviews, With introductions by A. JACOBI, M.D., LL.D., and I. L. NASCHER, M.D. Second Edition, Revised and Enlarged. C. V. Mosby Company, St. Louis, 1924. Price, \$4.50

The book is an excellent outline of the management of the senile state. Treatment of disease in the aged must be based on the principle of restoration to what is normal in senility. Dosage differs. An excellent chapter appears on the hygiene of the aged—clothing, skin, bowels, tobacco, urinary retention, eyes exercises and work. Emphasis is laid on keeping the senile out of bed, especially when ill and post-operatively. Differentiation is made between physiologic senile mental impairment and senile dementia. Toxemia, blood pressure and arteriosclerosis are discussed. Drugs for the senile state and opotherapy (tissue extracts) are thoroughly discussed in a very optimistic, though not convincing manner. Many pathological states are gone into in detail, and the use of electricity, radium and surgery stressed.

A TEXT-BOOK OF PATHOLOGY By W. G. MACCALLUM. M.D. Third Edition, thoroughly revised. 1162 pages, 575 original illustrations. Philadelphia and London, W. B. Saunders Co., 1924. Cloth, \$10.00 net

This third edition equals the excellence of the preceding editions. Some alterations have been made in the arrangement of the subjects and in the subject matter. Additions to the text have brought the book up-to-date. Many illustrations have been added, and new ones have been substituted for old ones.

As is to be expected, rickets is handled from the Johns Hopkins point of view in a masterly manner. As a whole, the volume approaches an unusual standard of excellence and as such should prove a valuable fundamental treatise for students and practitioners. Of a work so well known and written by so eminent an authority further comment is superfluous.

MAX LEDERER

FEEDING, DIET AND THE GENERAL CARE OF CHILDREN A Book for Mothers and Trained Nurses. By ALBERT J. BELL, M.D. Second revised edition. Illustrated. F. A. Davis Co., Philadelphia, 1924. Price, \$2.00 net

In this book the author strikes a dominant note in the opening chapter, by impressing upon the mind of the mother the importance of breast nursing. By saying it briefly and in a language understandable by any mother he establishes a *raison d'être* for his little book.

The medical man in recommending this little book to a prospective mother will do well to endorse chapter 11 and 12. This will serve the right direction in the path of preventive medicine. This is also true of chapters 18 and 19 which deal with Child Hygiene, a which every "unspoiled" mother should be advised to memorize. The more experienced "know it all" mother may be convinced if she can be made to read it.

The feature chapter—on Dentistry—is somewhat ultra modern, especially the recommendation to submit even child of 6 to an X-ray examination of his teeth, in order "to detect possible irregularities" in that part of the child's anatomy.

Chapter 36, on food preparations and solutions, is useful and practical for both the mother as well as the nurse.

One also finds here a rather good variety of formulas, their approximate measures and caloric values.

A good portion of this book is devoted to the brief discussion of diseases, from Pinworms to Meningitis, Poliomylitis, Scarlet, Intussusception, etc., giving the symptoms and general characteristics which of course may not be of interest to mothers but the trained nurse will find it helpful, especially the "Pediatric Nurse".

The reviewer hopes the future will produce more such books in order thereby to stimulate and encourage the "Pediatric Nurse".

It is a helpful little book and certainly more modern than most of the other books in its class and deserves the endorsement of the general practitioner as well as the Pediatrician.

HARRY APPEL

BACTERIA IN RELATION TO MAN A Study-Text in General Microbiology. By JEAN BROADHURST, Ph.D. Octavo of 306 pages, with 147 illustrations. Philadelphia and London, J. B. Lippincott Company, 1924. Cloth, \$3.00 (Lippincott's Nursing Manuals)

This book is an excellent laboratory outline of general microbiology, but not in the reviewer's opinion exactly fitted to the needs of a student nurse in the ordinary hospital. Its scope is general, not limited merely to pathogenic bacteria, but to the wider relations, helpful as well as harmful of bacteria to man. As a preliminary the author takes up the plant cell and plant in general, and then goes into the study of the characteristics of the various bacteria, methods of disinfection, air, water, milk, and nitrogen cycle, and relation to disease. This latter subject is only lightly touched upon, as is also the subject of immunity.

I COHN

PNEUMONIA. Its Pathology, Diagnosis, Prognosis and Treatment. By the late R. MURRAY LESLIE, M.A., B.Sc., M.D. Edited and revised by J. BROWNING ALEXANDER, M.D., M.R.C.P. (Lond.) Octavo of 351 pages. London, William Heinemann 1924. Cloth, fl 2s. 6d.

Used posthumously in 1925 after editing by J. Browning Alexander. Physician to St. Mark's Hospital in London, this volume of 350 pages presents in succinct form an account of pneumonia from the earliest days of medicine to the present. It is of interest because the subject is rarely handled in this way and because the material is so well presented the author calling upon his experience of many years as Senior Physician to the Prince of Wales General Hospital and to the Royal Chest Hospital of London.

In turn, the nomenclature of the disease its bacteriology, classification, typical forms, etiology, sources of infection, channels of infection, pathology, symptomatology and phenomena of crisis and lysis are thoroughly considered.

Discussion is presented in attractive form and easily holds the attention. The chapters dealing with treatment are valuable, those relating to alcohol, opium and digitalis are thorough in their scope and broader in their concept than in standard text books.

Such a volume as this is unusual and worthwhile so few thorough discussions of the subject being presented in English.

FRANK BETHEL CROSS

THE AMERICAN ILLUSTRATED MEDICAL DICTIONARY. A New and Complete Dictionary of the Terms Used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, Nursing, Veterinary Science, Biology, Medical Biography etc. with the Pronunciation Derivation and Definition including Much Collateral information of an encyclopedic character. Thirteenth Edition revised and enlarged. By W. A. NEWMAN. Octavo of 1344 pages with 338 illustrations in color. Philadelphia and London W. B. Saunders Company 1925. Flexible binding \$7.00, thumb index, \$7.50.

The thirteenth edition follows the same general line as the previous editions, the important feature being the addition of about 2500 new words. Many of these words can be found in no other dictionary. The general excellence of this book, together with the fact that it is just off the press, should recommend it to the profession as probably the best medical dictionary available at the present time.

FREDERIC DAVALL

RADIUM. Its Therapeutic Uses in General Practice. By G. H. VARLEY, M.D. (Oxon). 12mo of 103 pages. London Humphrey Milford New York Oxford University Press 1924. Cloth \$1.75.

In this little work Dr. Varley has given a detailed account of his experience in the use of radium in his own general practice, including everything from corns to cancer of the stomach—in all some 150 cases. His statements are frank, his cases well studied and the results fully described. Dr. Varley has been careful to supply his exact technique and dosage in each case, thereby enhancing the value of his book to the radiologist. It must be remembered however that all of his radium was in the form of the bromide which is approximately half the strength of the sulphate of radium in which the form radium is used in America. The first part of the book is given over to the history of radium and its proper methods of application and dosage.

We shall look forward to a subsequent book which Dr. Varley has promised in his introductory remarks.

NATHAN T. BEERS

A TEXT-BOOK OF GENERAL BACTERIOLOGY. By EDWIN J. JOHAN, Ph.D. Eighth edition, thoroughly revised. Octavo of 722 pages, fully illustrated. Philadelphia and London W. B. Saunders Co. 1924. Cloth \$5.00.

This book is so well known that it needs no introduction. It is as always compact, practical, thorough and useful. The subject is covered in the usual way with discussions of methods, principles, genera and characters on all the pathogenic bacteria. There are also chapters on alterable viruses, bacteria in milk, soil and water, diseases of plants and diseases of probable bacterial origin. The author records recent advances in this science by discussing the bacteriophage, tularemia and the discoveries in scarlet fever. He also devotes many pages to the antibiotics.

E. B. SMITH

A MANUAL OF GYNECOLOGY. By JOHN COOKE HIRST, M.D., F.R.C.S. Second edition, revised. 12mo of 308 pages with 195 illustrations. Philadelphia and London W. B. Saunders Company 1925. Cloth \$3.50.

The text is presented in the manner used by the author in teaching the subject during the past twenty years. In several sections the matter has been considered from the combined obstetrical and gynecological viewpoint. To present it in any other way would be at the expense of thoroughness and clarity. Throughout the book an effort has been made to omit unprofitable discussion and to give to the reader at least one method of treatment which has proven its value as a basis on which to build is suggested by the individual's own experience. Special chapters deal with leucorrhea and backache. The causes of the latter are thoroughly discussed but with vague suggestions to remedy it. Leucorrhea is given considerable space particularly the treatment. After a trial of each remedy suggested the leucorrhea will probably be still present. We note in the treatment of the climacteric the use of the ancient and decrepid valerianates. The reader however is warned of their "terrible smell."

As a manual it serves its purpose admirably.

F. B. DOYLE

COMMON DISORDERS AND DISEASES OF CHILDHOOD. By GEORGE FREDERICK STILL, M.A., M.D., F.R.C.P. Fourth Edition. Octavo of 905 pages with illustrations. London Humphrey Milford New York Oxford University Press 1924. Cloth \$7.50.

The fourth edition remains true to the stated plan of the author in his first edition, namely, not to attempt to present a systematic treatise or text-book but rather to be selective and discursive as it suited his bent.

As the very title of the book implies the theme is the everyday and commonplace disorders which bulk most largely in the out-patient and in-patient clinics of a children's hospital.

The original plan was to put together lectures delivered at King's College Hospital and at the Hospital for Sick Children in Great Ormond Street, London, and with these were combined other clinical studies written at various times for other purposes.

The lapse of eight years, since the appearance of the third edition, made it seem wise to revise and bring the text up to date, and new chapters have been added on blood diseases, purpura and some purely symptomatic occurrences such as headaches, giddiness and loss of weight in children past the age of infancy.

No visit to London is complete for any one interested in pediatrics without a visit to Great Ormond Street where Dr. Still and his assistants give clinics which are as remarkable for their clarity and simplicity as for their thoroughness.

The author is fortunate in being able to write as he talks and the same thoroughness and simplicity mark the text of his book as his bedside and clinical talks.

WM. HENRY DONNELLY

SYMPTOMS OF VISCERAL DISEASE A Study of the Vegetative Nervous System in Its Relationship to Clinical Medicine By FRANCIS MARION PORTNOR, M.D., LL.D., F.A.C.P. Third Edition Eighty-six Illustrations Ten Color Plates The C V Mosby Co., 1925 Price, \$650

This book might well be called 'The Vegetative Nervous System in Health and Disease.' Much of the interesting data on this important subsidiary of the central nervous system is incorporated in the book. The fundamental principles of the physiology of the system are repeated so often under various subheadings that they cannot be missed. The author uses italics freely, which always detracts from the value of a book. The value of the book could be enhanced many fold if the repetitions were removed, and as a consequence the book could be reduced to about 100 pages. The very interesting explanation of many visceral symptoms would thus be more compact, and one would not tire so soon in an endeavor to get to the end of the journey.

J ARTHUR BUCHANAN

THE INTERNATIONAL MEDICAL ANNUAL A Year Book of Treatment and Practitioner's Index. Forty-third year, 1925 William Wood and Co., New York Price \$5.00

The present issue is the forty-third appearance of a year book of medical and surgical treatment, and while it purports to be of an international nature, it is overwhelmingly English in its list of contributors and in the articles reviewed.

Of about thirty collaborators one notes but four Americans, namely, A W Adson of Rochester, E. Wyllis Andrews and Edmund Andrews of Chicago, and J Ramsay Hunt of New York.

Many valuable and interesting articles are reviewed, one which seemed of special attraction was from the *Presse Medicale* describing the use of lipiodol by intratracheal injection for X-ray diagnosis of pulmonary conditions, especially bronchiectasis.

Books of this kind are of particular value to the busy practitioner who has not the time to read all the current literature during the year and who is anxious to keep abreast of the times by having the outstanding writings summarized for him.

The vitally important part of a year book is naturally the index, and in this case it is commendably good.

LYMPHATIC DRAINAGE *

By Dr W A. COSTAIN, M B,

Department of Surgery University of Toronto
TORONTO, CAN

THE operation of draining the thoracic duct in the neck is a new surgical procedure which is designed to overcome the septic absorption which occurs in diffuse peritonitis.

The rationale of the operation is that in peritonitis, septic absorption occurs through the lymphatics into the thoracic duct, and by ligating and opening this structure in the left side of the neck the products of septic absorption are prevented from entering the blood stream and are drained away from the wound.

In advocating this operation one assumes that it is the products of septic absorption which give rise to those symptoms in peritonitis, generally regarded as complications, namely: obstipation, distension, vomiting, cyanosis, etc.

The septic products which produce these symptoms are contained in the lymph which is continually pouring into the blood stream in large quantities. One does not realize the extent of this fluid contribution to the blood until the flow from the duct has been actually seen. An estimation of two quarts in twenty-four hours has been made.

In peritonitis that fluid is coming from two septic sources: one is the peritoneal cavity and the infected tissue spaces, through the lymphatics proper, and the other is the lumen of the bowel, through the lacteals. The composite nature of the lymphatics of the abdominal cavity is indicated in Figure I.

The fluid absorbed from the lumen of the bowel, through the lacteals, is extremely toxic in character and is a factor of the utmost importance in peritonitis. It affords an explanation of the verging of symptoms of diffuse peritonitis and other acute abdominal conditions into one clinical picture.

The paths of lymphatic flow are well shown in the accompanying figures. Figure 2 is an X-ray picture of a dog's small intestine in which

some of the lymphatic vessels of the mesentery were injected with quick-silver before the dog was sacrificed. The mercury in each case flowed up to the glands at the root of the mesentery and stopped, being too large to pass the glands. Injection could only be made upwards with the lymph stream on account of the numerous valves which prevented retrograde injection. Figure 3 shows a comparison between the size of the lymph vessels and the branches of the superior mesenteric artery. Figure 4 is an X-ray of a dog in which the injection was made proximal to the glands in the root of the mesentery. In this dog the mercury not only filled the lymphatics, but flowed into the circulation where some is seen in the right auricle and in arteries of the abdominal cavity. Figure 5 is a similar picture showing injections in the mesentery and the proximal side of the glands up to the outlet of the duct in the neck. Figure 6 shows a dissection of a dog's thoracic duct, injected with mercury. The duct is double in the major part of its extent. This happens occasionally in the human thoracic duct and is due to an arrest of the embryological development. Figures 7, 8, 9, and 10 are drawings of the human lymphatics. The relations of the duct in the neck are clearly shown. In a young individual the duct is higher in the neck than in the adult where it is usually slightly above or even behind the clavicle.

The experimentation upon which this operation was based consisted in ligating the appendix in dogs, as shown in Figure II, the base of the appendix and the mesoappendix being ligated separately with double chromic catgut ligatures. The abdomen was then closed, and it was found that the dogs died in about two days. What happened was the appendix swelled up becoming gangrenous and filled with black highly infective fluid, and before walling off could occur ruptured into the peritoneal cavity causing a fatal diffuse peritonitis. When, however, this procedure was supplemented, after twenty-four hours, by a suc-

* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse May 13, 1925.

MIDWIFERY MECHANICS By LIEUT-COLONEL ANDREW BUCHANAN, I.M.S. (Retd.), M.A., M.D., M.Ch., M.A.O. Octavo of 82 pages with illustrations. London, Humphrey Milford, New York, Oxford University Press, 1924. Cloth, \$2 50

This little book is an ingenious explanation of the mechanism of delivery, based upon the author's "theory of the pivot points." The difficulty in occipito posterior positions is due, he says, not to a long diameter of engagement but because the pivot points are not altogether. Many drawings of his models seem to make his exposition of this subject as clear as a problem in geometry. Although difficult to follow without models the story is very interesting to a student of obstetrics.

C. A. G.

INSECTS AND DISEASES OF MAN By CARROLL FOX, M.D. Octavo of 349 pages, with 92 illustrations. Philadelphia, P. Blakiston's Son and Company, 1925. Cloth, \$4 00

This book aims to present the subject of medical entomology in a practical manner, which is especially suitable for physicians, health officers, as well as entomologists. The field is a large one and the material cannot be treated in an exhaustive manner and, in fact, this is not the intention of the author, who "aims rather to give only the essentials for public health practice which may be found to be helpful and worth while." In this, Dr. Fox has been remarkably successful. He has written a volume which, with the descriptions accompanying the many excellent illustrations, will allow the reader to become quickly familiar and sufficiently conversant with the subject without the unnecessary expenditure of time and the reading of a much larger amount of material.

The first part deals with the classification, identification, anatomy, life history, general considerations, key to sub families, etc. The second part discusses the diseases which are carried by anthropods among human beings.

JOSEPH C. REGAN

APPROACHING MOTHERHOOD Questions and Answers of Maternity. By GEORGE L. BRODHEAD, M.D. Second Edition. 12mo of 193 pages. New York, Paul B. Hoeber, Inc., 1925. Cloth, \$1 50

This is the second edition of a little book which well deserves its popularity. Written for the prospective mother in the form of questions and answers, it meets her needs perfectly. Here and there are blank pages on which to write questions for the doctor. A handy volume, and one that might be read with much profit by those who call themselves practical nurses. At present popular fallacy, superstition and hearsay make up a large part of their knowledge. Here is a real opportunity for them, as well as for the young mother.

C. A. G.

LOCAL ANESTHESIA SIMPLIFIED By JOHN JACOB POSNER, D.D.S., New York Chief Dental Department Harlem Dispensary. Fifty-five illustrations. The C. V. Mosby Co., St. Louis, Mo. 1924. Price \$3 50

In a very logical manner, the author guides the reader to the most practical methods of controlling pain and so makes it possible for the dentist to perform with ease the most difficult and painful operations.

Rightly, the author makes a strong plea for a better method of infiltration anaesthesia in the maxilla and calls it "Supraperiosteal Injection."

He prefers this simple method rather than the indiscriminate use of conduction anaesthesia in the maxilla which carries the potentialities of serious complications.

The short text, with its many illustrations, gives a complete story of Local Anaesthesia and makes this book a well needed little volume for the busy practitioner.

VICTOR STOLL

OCULAR THERAPEUTICS A Manual for the Student and the Practitioner. By ERNST FRANKE, M.D. Translated by CLARENCE LOEB, A.M., M.D. Oculist to The Michael Reese Hospital Chicago, Ill. The C. V. Mosby Co., St. Louis, 1925. Price \$3 50

The book is divided into two parts, the first of which takes up general and local treatment of eye conditions and the second the treatment of the special structures which go to make up the eye and its appendages. In the chapter dealing with general treatment, tuberculosis is given first consideration. The manner of the curative action of tuberculin and the dosage of the various kinds used—old, new and bacillary emulsion—together with its administration subcutaneously, percutaneously and intracutaneously, are given in detail. Syphilis is taken up in a similar manner, special attention being paid to the use of some of the newer forms of arsenic and mercury. Serum therapy and the use of milk and other agents in the so-called "irritative treatment," combined with a description of the manner of employment of the various forms of light, electricity, heat, baths, etc., help complete this chapter. Local treatment is dealt with under the following headings: mechanical, warmth and cold, light and ray, medical serum and electrical. The concluding chapter deals with the treatment of the various conditions affecting the individual structures which enter into the formation of the eye. The manner in which the subject matter is arranged makes the book of great value, as the reader can obtain the relative merit of every therapeutic measure by perusing the first chapter and by referring to the second chapter the application of these methods are shown in the treatment of the conditions which constitute the practice of ophthalmology.

WM. F. C. STEINBUGLER

PHYSIO-THERAPY IN GENERAL PRACTICE, AND FOR THE USE OF MASSEUSES By E. BELLIS CLAYTON, M.B., B.Ch. (Cantab.) Director Physio-Therapeutic Department, Kings College Hospital, London. William Wood and Co., New York, 1924. Price, \$3 50

An excellent little volume which can be highly recommended to the entire medical profession.

The simplicity and preciseness of the text makes the little book very valuable to readers who have not even a rudimentary knowledge of this form of therapy.

Chapters II and III dealing with the after care of injuries is replete with most modern thoughts, especially can be mentioned the point that struck the reviewer's attention in his recent visit to the British clinics. That is of promoting muscular activity by first producing a relaxation of the antagonistic muscles.

Other chapters dwell upon useful, physical aids in deformities of the spine and extremities, in respiratory diseases, abdominal treatments, arthritis and diseases of the nervous system.

It is a very valuable guide for those who desire to lay a firm foundation on which to build a knowledge of physio-therapy.

B. KOVEN

AN INDEX OF TREATMENT By Various Writers. Edited by ROBERT HUTCHINSON, M.D., F.R.C.P., Physician London Hospital, and JAMES SHERREN, C.B.E., F.R.C.S., Surgeon London Hospital. Ninth Edition. Revised and Enlarged. William Wood and Co., New York, 1925. Price, \$12 00

This is a typical English product—one might say an essentially English product in that it presents an epitome of the teachings and practice in the London Hospitals. Here is presented an immense amount of well written detail about almost every pathologic process known to medicine.

The numerous contributors are especially able, by their positions and experience, to present their subjects thoroughly, and do so in very facile manner. The American profession will welcome this book as a companion to the best it has.

results are the best. They show that when the duct drainage is resorted to soon after the first operative procedure, the results are also good. But when an extended period intervenes between the initial procedure and the duct drainage, the results may be almost negative. This is what might be expected, for draining the thoracic duct will not influence the toxæmia which has been allowed to continue a long time for then it has too firm a hold upon the patient. The operation should be chosen early for it will not produce a miracle upon a moribund patient.

At this time it is rather early to quote figures as only a comparatively few operations have been done, and these have all been on the so-called hopeless cases. However, the records of sixteen cases which I have been able to collect and which are appended, show that the mortality rate of these cases has been reduced thirty to forty per cent.

The following cases comprise those reported in various medical journals and others not reported.

Case 1—Female, age 9. Pneumococcic peritonitis. Lymphaticostomy, October 10, 1922, under intratracheal ether. Half a cubic centimeter of pus was aspirated from the right side of the peritoneal cavity for examination and contained pneumococcus IV. The patient was exsanguinated and transfused 600 cubic centimeters being drawn off and 800 cubic centimeters introduced. Culture from the duct fluid was sterile as was also the blood culture. Lymph drained for three days. Voluntary bowel movement on second day. Gauze removed on second day, rubber tube on the sixth when the patient was sitting up on soft diet. Rapid recovery. Discharged cured on October 30. Today she is in perfect health with a normal abdomen and a scar on the neck which is hardly noticeable (Dr Costain⁴).

Case 2—Female, age 17. Puerperal peritonitis. Lymphaticostomy May 14, 1923, under one per cent novocaine. Culture and smears from the duct contained pneumococci. Blood culture negative. Free duct drainage for four days. Rapid recovery. Discharged cured on July 4 (Dr Edwards⁵).

FIG. X

FIG. XI

cessful drainage of the duct the dogs recovered.

The experimentation has been repeated by other observers on two occasions. Dr. Newman and Prot. Wells reported¹ a series of experiments in which the results were almost identical with my own. Drs. Lehman and Copher recently reported² experiments in which the results were directly opposite, not one of their duct operations being successful. They, however, employed a different method of draining the duct, that of ligating and severing the duct instead of merely opening it. What happens when the duct is divided is that the proximal cut end retracts into the mediastinum, on account of the action of the involuntary muscle fibres in the duct, and death is hastened. Their work is of importance in that it indicates that division of the duct must not be undertaken.

The operation itself is best done with local anaesthesia, except in young children where this may not be feasible. Little or no anaesthesia is required beneath the skin. Figures 12, 13, and 14 are drawings of different stages of the operation. When the duct is secured a single strand of plain catgut is used to ligate it a short distance from the vein. A longitudinal incision about one quarter to half an inch long is made on the abdominal side of the ligature. If the duct is sufficiently large a V-shaped incision may give better

drainage. A narrow strand of rubber tissue, or a strand of silk-wormgut is passed down the duct a short distance. Sometimes this is impossible on account of the presence of a valve. The loose ends of the catgut ligature and the drain in the duct are secured to the skin, leaving sufficient length for retraction. Narrow plain gauze is loosely applied around the duct and out of the wound. A soft rubber tube is placed to keep the wound open and the wound is partially closed. The dressings are kept moist with normal saline or sodium citrate solution. The gauze is carefully replaced on the second day. The rubber tube and duct drain are left until a sinus has formed.

In the after treatment the feature of greatest importance is the giving of fluids, especially by mouth, in order to ensure a continual flow of lymph. The introduction of tap-water into the intestine has been shown to cause a rapid marked increase in the flow of lymph from the duct.³

The operation has been performed by various operators in cases of pneumococcic peritonitis, appendiceal peritonitis, perforated duodenal ulcer, puerperal peritonitis, perforated gastric ulcer, and ruptured intestine. In practically all of the cases it was noted that there was a rapid marked improvement in the patient's condition following the duct operation. The sooner it was done the better were the results. This fact is best shown by instancing six of the above cases: three in pneumococcic, and three in appendiceal peritonitis.

Case 1—Pneumococcic peritonitis. Duct drained as a single procedure when the diagnosis was made. Rapid recovery.

Case 10—Pneumococcic peritonitis. Abdomen opened and after diagnosis was confirmed the abdomen was drained and the duct operation done. Recovery.

Case 8—Pneumococcic peritonitis. Abdomen drained. Thirteen days later on recurrence of symptoms the duct was drained. Death in nine days.

Case 3—Appendiceal peritonitis. Abdomen opened and the appendix removed. Practically no pus formation. Abdomen closed and duct drained. Rapid recovery.

Case 7—Appendiceal peritonitis. Abdomen opened and appendix removed. Abdomen drained on account of pus. One day later the duct was drained. Good recovery.

Case 13—Appendiceal peritonitis. Abdomen opened and drained on account of pus. Appendix was not removed. One week later when the patient was in extremis the duct operation was done. Death in thirteen days.

These six cases indicate that when the duct drainage is done, upon the establishment of the diagnosis, either as a single measure or along with whatever other procedure is necessary, the

estimation of the quantity of lymph drainage was several quarts in twenty-four hours. Distension was greatly reduced and patient was taking fluids. On September 10 the lymph flow lessened markedly and patient had some return of symptoms. Castor oil was given. Next day there was a little drainage from the duct. Patient felt better. Bowel moved and there was considerable discharge from the opening in the bowel. The feces coming from the fistula were alkaline in reaction. On September 16 the patient's general condition was so much improved that it was thought he would recover. Three days later he developed a hiccough with a return of abdominal symptoms indicating a continuation of disease around the appendix. His condition excluded any possibility of further operative procedure and he died on September 20, thirteen days after lymphaticostomy. At post mortem the appendix was found leaking fecal matter into a large abscess extending up to the diaphragm. The remainder of the abdomen, save around the drainage wound, was normal in appearance, except for some loose adhesions. No other pathology was found (Dr Costain).

Case 14 Female adult. Seen in collaboration with a gynaecological colleague. Patient had a septic peritonitis with large quantities of gas in the peritoneum following a septic puerperium. The duct was opened and the abdomen drained. The patient lived three weeks and ultimately died of septic pneumonia. There was certainly marked improvement following the drainage of the duct (Dr Cooke).

Case 15 Male, age 32. Perforated duodenal ulcer with diffuse peritonitis. Seen a week after the abdomen had been drained. There was cyanosis, great distension and fecal vomiting. No

peristaltic action could be detected. Lymphaticostomy on January 5, 1925, under one half per cent novocaine for the skin. Very little lymph flowed on opening the duct. The duct failed to drain and there was no improvement in the patient's condition. He died on the second day. No post mortem (Dr Costain).

Case 16 Female, age 5. Perforated appendix with diffuse peritonitis. The abdominal condition was dealt with and then the duct was drained only in small quantities. The child made a good recovery (Dr Cooke.)

One observes, from a survey of these cases, that the average length of time of duct drainage was five days. In one case where the duct failed to drain there was no change in the patient's condition. Organisms were found in the duct fluid in two cases. This finding, however, is of secondary importance for it is the toxins flowing through the duct which lead to a fatal termination in peritonitis.

POLYCYSTIC DISEASE OF THE KIDNEYS—REPORT OF SIX CASES*

By JOSEPH SCHWARTZ, M. D.,

NEW YORK CITY

BY polycystic disease or degeneration of the kidneys, we understand a congenital maldevelopment in which one or, more commonly, both kidneys show a conglomeration of cysts, separated by fibrous septa or compressed kidney tissue.

It is an exceedingly interesting lesion of the kidneys, as its similarity in its clinical manifestations to other renal lesions may be so striking as to lead to errors in diagnosis. The condition is not common, but yet by no means as infrequent as formerly supposed. Its frequency may be inferred from the report of Preitz, at Keil University, who found it 16 times in 10,000 autop-

sies, and Garceau, at the Boston City Hospital, who found it 10 times in 2,429 autopsies. Still others believe it occurs more frequently. Our improved diagnostic acumen and clinical sense have greatly enhanced our means of recognizing them. Yet, in spite of this, owing to its atypical manifestation in some individuals and lack of symptoms in others, autopsies, much to our chagrin, have on repeated occasions revealed their presence in individuals unsuspected of this malady.

I wish to report six cases admitted to Lebanon Hospital, five females, including one new-born, and one male. In only three was the diagnosis definitely established clinically. In two others it was suspected while in the last it was an accidental finding at the autopsy.

*From the Surgical Service and Department of Pathology, Lebanon Hospital.

Case 3—Male, age 48 Perforated appendix with diffuse peritonitis Midline incision and appendix removed There were only slight smears of pus so the abdomen was closed Recovery in this case was considered almost out of the question so a lymphaticostomy was done after the abdomen had been closed The operation was performed on April 15, 1924 Culture of the lymph was sterile Free duct drainage for seven days when there was sudden diminution and a discharge of pus from the abdominal wound Good recovery Discharged with both wounds healed on May 10 (Dr Cooke⁶)

Case 4—Male, age 32 Perforated appendix with diffuse peritonitis Appendix removed and abdomen closed Three days later duct was drained Death six hours later (Dr Colin Mackenzie⁷)

Case 5—Male, age 43 Perforated duodenal ulcer Thirty-six hours duration Abdomen opened and perforation closed and protected by omental graft Abdomen closed Lymphaticostomy Good recovery (Dr Colin Mackenzie)

Case 6—Male, age 51 Perforated gastric ulcer Fourteen hours duration Patient desperately ill Opened abdomen and closed ulcer Omental graft Lymphaticostomy Death in four hours (Dr Colin Mackenzie)

Case 7—Male, age 10 Perforated appendix with diffuse peritonitis The abdomen had been opened a day before, the appendix removed and the abdomen and ileum, close to the caecum, drained Lymphaticostomy under nitrous oxide and oxygen on April 21, 1924 The duct drained for five days Good recovery (Dr Costain⁸)

Case 8—Female, age 4 Pneumococcal peritonitis Abdomen drained on February 20, 1924 Improvement for a week and then a recurrence of symptoms Lymphaticostomy on March 5 The duct drained freely There followed a marked improvement in the patient's general condition The distension and tenderness disappeared This improvement continued for five days, during which time a very free discharge of lymph was observed from the neck wound, although the small drain had been removed from the opening into the duct It was then noticed that, although the abdominal condition appeared to be most satisfactory and the child was taking abundant nourishment by the mouth, she seemed to be getting weaker and to be losing weight rapidly On March 14, nine days after the lymphaticostomy had been performed, death took place Lymph was discharging freely up till shortly before the child died In the lymph taken immediately on opening the duct no organisms were present No post mortem was done (Dr Alex Mitchell⁹)

Case 9—Male, age 48 Ruptured intestine Injured underground sixty hours before admission to hospital Live dullness absent Operation on May 9, 1924 On opening the abdomen

the intestine was found matted together with sticky, flaky adhesions, and any hope of finding the rupture was rapidly abandoned A small tube was placed in the nearest loop of distended gut, which was small intestine fairly high up, and another tube in the pelvis for peritoneal drainage As a spinal injection was used, very little ether was required, and practically none was required to perform the lymphaticostomy Temporary improvement and free drainage from the duct occurred for fifteen hours, when the pulse began to increase and the patient died twenty-four hours after operation (Dr D A Mitchell¹⁰)

Case 10—Female, age 10 Pneumococcal peritonitis Abdomen opened and on confirmation of diagnosis, drained, and lymphaticostomy done Free drainage from the duct occurred and the patient made a good recovery (Dr R I Harns, Toronto)

Case 11—Female, age 5 Diffuse peritonitis of obscure origin, thought to be appendiceal Unfortunately a gridiron incision was made and an inflamed, but not perforated appendix found and removed The abdomen was drained Three days later lymphaticostomy was performed Free drainage and undoubted improvement occurred for twenty-four hours, and the drainage continued very free up to the time of death, forty-four hours after the operation (Dr D A Mitchell)

Case 12—Female adult Lower abdominal infection Moribund on admission Abdomen drained and one day later lymphaticostomy was performed There was free discharge of lymph and a little improvement for a day when the patient died Culture from the lymph taken at the time of operation showed *B. coli*, *Streptococcus* and *B. pyocyaneus* No post mortem done (Dr Alex Mitchell)

Case 13 Male, age 47 Diffuse peritonitis from perforated appendix Abdomen had been opened in the midline and drained It had been thought wise not to attempt to remove the appendix Seen a week later, in extremis, and duct operation was done, though it was thought he could not survive The operation was done on September 7, 1924, and no anaesthetic was necessary Lymph flowed freely and coagulated rapidly Morphine was given at intervals to keep him at rest Saline interstitially and saline with glucose per rectum Water by mouth Next day he said he felt ten times better Lymph was flowing freely It was slightly greenish and coagulated rapidly To hasten recovery it was thought advisable to open the lowest coil of small intestine presenting in the abdominal wound which had been forced open prior to the duct drainage, by the extreme distension A tension suture had already partially cut through the intestine and this opening was enlarged allowing escape of feces and gas On September 9 au

past few months he was always well. Family history is negative. On examination, the man appeared in good health and rather obese. In the right side of the abdominal cavity was palpated a large mass extending from the ribs to the crest of the ilium and reaching to the left of the umbilicus. It was hard, smooth and painless. Temperature, pulse, respiration were normal. Laboratory findings: Blood and Wassermann negative. Urine contained a trace of albumin, sugar 11%, no casts or blood. Phenolphthalein 20% first hour, 50% second hour. Blood chemistry: N P N 50 mg per 100 cc of blood. Urea 28 mg. Uric acid 4.5 mg. Cholesterol 1.4 mg, creatinine 2mg, sugar 160 mg. Blood pressure 160 systolic, 100 diastolic.

The following conditions were considered: retroperitoneal sarcoma, kidney tumor and cystic kidney. An exploratory was done on August 16, 1923, through a right rectus incision at the level of the umbilicus. The colon was found pushed anteriorly and to the left. On approach of this mass it was discovered that we were confronted with a polycystic kidney. On palpation of the other kidney it was found to be much smaller, but also polycystic. No surgical procedure was instituted. The abdomen was closed in the usual manner. The day following the operation there developed subcutaneous emphysema in the area surrounding the incision. Some fluctuation was also present. Another incision over this area disclosed the presence of a sero sanguinous fluid, the culture of which proved negative. The emphysema spread rapidly downwards, involving the scrotum, which became gangrenous and foul smelling in a few hours. Temperature rose to 104° and pulse rate to 120. The patient was desperately ill and died several hours later from what appeared clinically a gas bacillus infection. Cultures under aerobic and anaerobic conditions failed to show the presence of any organism. An autopsy disclosed the right kidney several times the normal size, weighing 1,300 gms (Fig 2). At each pole is a large cyst about the size of a small grape fruit. In between there is apparently normal kidney substance, studded here and there with small cysts. The left kidney weighed 750 gms and contained many cysts separated by normal looking kidney tissues. The microscopic section showed the presence of many cysts separated by renal tissue showing minimal changes. Were it not for this unusual and rare post operative complication, this patient might have survived for an indefinite period.

Case 5

R. S. Female, married, age 44, admitted June 3, 1923, complaining of pain in the lumbar region, headache, nausea, vomiting and bloody urination. Her family and personal history were negative. She had five children, all living and well. Her present trouble she attributes to a cold con-

FIG 2

tracted three months prior to her entrance to the hospital. From then on she experienced daily headaches and loss of appetite. At times she would feel nauseated and would vomit. For about two weeks before admission there developed a dull pain in both lumbar regions. This would at times radiate to the groin, when she would also notice that her urine was decidedly blood tinged.

On examination she appeared very pale, emaciated and sick. Temperature 101°, pulse 100. Head and chest were negative. In the right abdominal quadrant, immediately below the liver, was palpated an irregular mass the size of an orange, which was tender and movable on respiration. On the left side, also corresponding to the kidney, a smaller mass was felt. There was marked costo-vertebral tenderness. No edema of extremities. Laboratory findings: Urine contained a heavy trace of albumin, hyaline and granular casts, pus and blood. Phenolphthalein, 5% first hour, 10% second hour. Blood, R. B. C 3,500,000, W. B. C 12,000, polys 82%, lymphs 18%. Wassermann was negative. Blood chemistry: N P N 173 mg per 100 cc of blood, urea 111 mg, uric acid 11 mg, creatinine 3.3 mg, sugar 1.43. Blood pressure, 160 systolic, 100 diastolic. Before death the systolic rose to 200 and diastolic 110.

Cystoscopy revealed blood coming from both kidneys. Through a ureteral catheter, I injected 7 cc of a 20% solution of sodium bromide into the pelvis of the right kidney. The pyelogram showed a filling defect of the lower calyces, suggesting the possibility of a new growth. In view of this bilateral mass we were inclined to believe this condition as polycystic disease of the kidneys. During her three weeks' stay at the hospital she became progressively worse and finally lapsed into coma and died.

The autopsy revealed two large polycystic kidneys, with hemorrhage and suppuration in many of the cysts (Fig 3).

Case 1

B G An infant which died one hour after birth. It was a female full-term baby—normal delivery. Immediately upon birth, the child began to breathe very feebly and with great difficulty. No cry could be induced. The mother, apparently in good health, had two previous children, one of which died soon after birth from a similar affection. The other child is living and well. The new-born appeared well developed, like any normal baby, but presented a large protuberant abdomen in which was palpated a mass the size of an orange in each flank. These tumors were round, regular, and filled the abdominal cavity. It was suspected that the infant had polycystic kidneys. The autopsy confirmed this opinion.

The kidneys were several times the normal size. The kidneys were regular and firm (Fig

FIG 1

1), each weighing approximately 250 gms. On cross section the appearance was like a fine sponge, the minute cysts of uniform size, the capsule was slightly adherent. The microscope revealed large spaces, apparently cystic dilatation of tubules lined with low cuboidal epithelial cells. They were separated by dense, richly cellular fibrous connective tissue in which were embedded many tubules of the embryonal type. Some normal appearing tubules and glomeruli were also seen scattered through the section. No other congenital anomalies were found.

Case 2

S N Female, married, age 67, admitted to Lebanon Hospital October 3, 1920. Her family and personal history were negative. She had no children. Two years ago she was at this hospital, treated for nephritis, and was discharged as improved after a two-week stay. Up to her present trouble she has lived with apparent comfort. Three days ago, she experienced a persistent headache, nausea and occasional vomiting. One day prior to admission, she became very drowsy and was inclined to sleep most of the day. On admission the patient was very drowsy and responded very poorly to questions. Eyegrounds showed an albuminuric retinitis.

Heart and lungs were negative. Abdomen was negative. Laboratory findings: Blood and Wassermann negative. Urine, Sp. Gr. 1013, contained a moderate amount of albumin, hyaline and granular casts. Phenol-phthalein was eliminated 5% first hour, 10% second hour. Blood pressure, 130 systolic, 75 diastolic. Blood chemistry, N P N 130 mg per 100 cc of blood. Urea 70 mg. Creatinine 4 mg. Uric acid 6 mg.

The diagnosis was obviously nephritis with impending uremic coma. Two days after admission she lapsed into coma and died. On post mortem, two polycystic kidneys slightly larger than normal were found. On microscopic section were seen large cystic spaces lined with flat epithelial cells. Separating these cysts were irregular fibrous bands showing a marked round cell infiltration. Embedded in these strands of connective tissue were atrophic glomeruli and tubules undergoing organization. The blood vessels showed marked thickening of all coats.

Case 3

F G Female, married, age 47, admitted to Lebanon Hospital October 10, 1922. Her family and personal history were negative. All of her three children are living and well. Her present illness began two weeks ago with pains in the lumbar region, headache and fever. Her pain up to the time of admission was increasing in severity and would at times radiate to the groin on the left side. There were chilly sensations at times. On admission her temperature was 102°, pulse 100. She presented two irregular masses, each the size of an orange, and corresponding to the kidneys. The left was very tender and elicited a positive Murphy sign. Laboratory findings: Blood W B C 13,000, poly 85%, lymph 15%. Urine contained trace of albumin, hyaline and granular casts, a moderate amount of pus cells and some red cells. Blood pressure systolic 140, diastolic 85. Blood chemistry normal. Cystoscopy and ureteral catheterization revealed pus and blood coming from left kidney. The condition was diagnosed as polycystic kidneys with an infection in the left. The patient appeared very ill and an immediate operation was deemed advisable. The left kidney was exposed through a lumbar incision, punctured all accessible cysts, some of which were infected and contained sanguinous fluid. The patient's convalescence was uneventful, so was discharged three weeks after the operation. The wound was almost entirely healed, except for a small discharging sinus. It was later ascertained that she died within six months of uremia.

Case 4

J S Male, age 61, admitted August 14, 1923, complaining of a large mass in the right of the abdomen and sense of weight. This tumor was accidentally discovered three weeks ago by a physician in the course of an examination. Except for an occasional attack of diarrhea, in the

past few months he was always well. Family history is negative. On examination, the man appeared in good health and rather obese. In the right side of the abdominal cavity was palpated a large mass extending from the ribs to the crest of the ilium and reaching to the left of the umbilicus. It was hard, smooth and painless. Temperature, pulse, respiration were normal. Laboratory findings: Blood and Wassermann negative. Urine contained a trace of albumin, sugar 11%, no casts or blood. Phenolphthalein 20% first hour, 50% second hour. Blood chemistry: N P N 50 mg per 100 cc of blood. Urea 28 mg. Uric acid 4.5 mg. Cholesterol 14 mg, creatinine 2mg, sugar 160 mg. Blood pressure 160 systolic, 100 diastolic.

The following conditions were considered: retroperitoneal sarcoma, kidney tumor and cystic kidney. An exploratory was done on August 16, 1923, through a right rectus incision at the level of the umbilicus. The colon was found pushed anteriorly and to the left. On approach of this mass it was discovered that we were confronted with a polycystic kidney. On palpation of the other kidney it was found to be much smaller, but also polycystic. No surgical procedure was instituted. The abdomen was closed in the usual manner. The day following the operation there developed subcutaneous emphysema in the area surrounding the incision. Some fluctuation was also present. Another incision over this area disclosed the presence of a sero sanguinous fluid, the culture of which proved negative. The emphysema spread rapidly downwards, involving the scrotum, which became gangrenous and foul smelling in a few hours. Temperature rose to 104° and pulse rate to 120. The patient was desperately ill and died several hours later from what appeared clinically a gas bacillus infection. Cultures under aerobic and anaerobic conditions failed to show the presence of any organism. An autopsy disclosed the right kidney several times the normal size, weighing 1,300 gms (Fig 2). At each pole is a large cyst about the size of a small grape fruit. In between there is apparently normal kidney substance, studded here and there with small cysts. The left kidney weighed 750 gms and contained many cysts separated by normal looking kidney tissues. The microscopic section showed the presence of many cysts separated by renal tissue showing minimal changes. Were it not for this unusual and rare post operative complication this patient might have survived for an indefinite period.

Case 5

R. S. Female, married, age 44, admitted June 3, 1923, complaining of pain in the lumbar region, headache, nausea, vomiting and bloody urination. Her family and personal history were negative. She had five children, all living and well. Her present trouble she attributes to a cold con-

FIG. 2

tracted three months prior to her entrance to the hospital. From then on she experienced daily headaches and loss of appetite. At times she would feel nauseated and would vomit. For about two weeks before admission there developed a dull pain in both lumbar regions. This would at times radiate to the groin, when she would also notice that her urine was decidedly blood tinged.

On examination she appeared very pale, emaciated and sick. Temperature 101°, pulse 100. Head and chest were negative. In the right abdominal quadrant, immediately below the liver, was palpated an irregular mass the size of an orange, which was tender and movable on respiration. On the left side, also corresponding to the kidney, a smaller mass was felt. There was marked costo-vertebral tenderness. No edema of extremities. Laboratory findings: Urine contained a heavy trace of albumin, hyaline and granular casts, pus and blood. Phenolphthalein, 5% first hour, 10% second hour. Blood, R B C 3,500,000, W B C 12,000, polys 82%, lymphs 18%. Wassermann was negative. Blood chemistry: N P N 173 mg per 100 cc of blood, urea 111 mg, uric acid 11 mg, creatinine 3.3 mg, sugar 143. Blood pressure, 160 systolic, 100 diastolic. Before death the systolic rose to 200 and diastolic 110.

Cystoscopy revealed blood coming from both kidneys. Through a ureteral catheter, I injected 7 cc of a 20% solution of sodium bromide into the pelvis of the right kidney. The pyelogram showed a filling defect of the lower calyces, suggesting the possibility of a new growth. In view of this bilateral mass, we were inclined to believe this condition as polycystic disease of the kidneys. During her three weeks' stay at the hospital she became progressively worse and finally lapsed into coma and died.

The autopsy revealed two large polycystic kidneys, with hemorrhage and suppuration in many of the cysts (Fig 3).

FIG 3

Case 6

H. M. Female, married, age 46, admitted April 5, 1924, complaining of headache, nausea, weakness and multiple abscesses of the body and scalp. Family history and personal history negative. She has two children living and well. For the past four years the patient was aware of the presence of two large tumors in her abdomen. This, however, caused her no discomfort and did not incapacitate her from her usual household duties. At times she would feel a sensation of weight in her abdomen. For the past few weeks she was troubled with daily persistent headaches. As a result her appetite was lost. So severe were her headaches that she would become nauseated and would even vomit. Two weeks prior to admission, abscesses developed on her body. On admission her temperature was 101, pulse 95. On her scalp was a large confluent abscess. Small abscesses were also present on the body and abdominal wall. Heart and lungs negative. Abdominal examination revealed two very large masses meeting in the mid line and filling the abdominal cavity. They were slightly irregular, not tender. Laboratory findings: Blood, W. B. C. 23,000, poly 95%, lymphs 5%, Wassermann negative. Urine contained a trace of albumin, no casts, blood or pus. Blood chemistry: N. P. N. 176 mg per 100 cc of blood, urea 115 mg, uric acid 7.5 mg, creatinine 3.6 mg, sugar 112 mg. Phenolphthalein secretion, 5% first hour, 15% second hour. Blood pressure, 144 systolic, 80 diastolic. It was quite obvious that the patient had polycystic kidneys. The infections on her head and body were incised and drained under local anesthesia. Her condition became progressively worse. Twitchings of the right side of the face and right upper and lower extremity developed. After appearing very drowsy, uremic coma developed and the patient died one week after admission.

On post mortem were found two enormously large cystic kidneys, each weighing approximately 1,650 gms (Fig 4). Many of the cysts contained blood and pus. The microscopic picture was similar to the previous case. The liver was brown, slightly enlarged, and contained many

FIG. 4

cysts under the capsule and deep in the substance of the liver. These cysts ranged in size from a pinhead to a grape. No other abnormalities were found.

ETIOLOGY

The origin of this most interesting pathological lesion has long been a subject of discussion and theoretical speculation. The literature is abundant with many theories concerning the genesis of these cysts, but most of these views have long been discarded because of the lack of sufficient evidence to support them. There still remain three outstanding views which claim many adherents: 1. Neoplastic, 2. Retention, 3. Congenital. Sabourin, in supporting the neoplastic theory, maintained that there was a primary cirrhosis of the kidney which compromised the epithelial cells, causing their proliferation into cysts. Nauwercck, Hufschmid and others believed it to be an adenocystoma, the primary lesion being a foetal adenoma with secondary cyst formation. Virchow, in advancing the retention theory, first claimed that the cysts were the result of an obstruction in the large collecting tubules by uric acid deposits. Later, he expounded the inflammatory origin of these cysts believing that there was an intrauterine nephritis which gave rise to an increase in connective tissue. The latter compromised the collecting tubules, causing their closure and retention of urine with subsequent cystic dilatation of the proximal part of the tubule.

The congenital theory seems to enjoy the greatest support and is being regarded more favorably by modern pathologists. Ribbert, Still and others were of the opinion that the lesion is due to a faulty embryological development.

where the metanephros has abnormally blended with the mesonephros which resulted in a failure of union between the convoluted and straight tubules

The age at which we commonly see these cases and at which they manifest themselves varies between 45 and 65. Cases have been observed at all ages. The youngest of our series was a new-born the oldest 67. Homney observed two cases at 88. It is more common in females. Of our six cases there were five females. Of Sieber's collected cases, there were 116 females and 82 males. In all of our cases both kidneys were involved. Luzzato noted its bilateral existence in 185 out of 226 cases. Sieber noted that it was bilateral in 140 of his cases. Several members of the same family may be affected, as in the case of the infant. A familial and hereditary tendency has been noted by many observers. Crawford reported a case of polycystic kidneys in whose family tree the condition was traced back four generations. Spreut cites a case of a woman with cystic kidneys, with five other members of the same family similarly affected.

SYMPTOMS

It may be of interest to note that these patients may be well advanced in years without symptoms referable to the urinary apparatus or even knowing that there is anything amiss with their kidneys. Eight such accidental findings occurred in Sieber's series, seven others in Ritchie's 88 collected cases.

Patients generally present themselves because of pain, hematuria, abdominal tumor, or more commonly in the terminal stage with symptoms of renal insufficiency manifesting itself in headache, anorexia, nausea and vomiting.

The pain is commonly described as dull ache or sense of weight in the back or abdomen. It may even be as severe as the pain accompanying the passage of a renal calculus thru the ureter. Tenderness and rigidity are present if complicated by infection of the cysts or pelvis of the kidney.

Hematuria occurs irregularly in about one third of all cases. It may be the first sign of a diseased kidney and often leads to an erroneous diagnosis of neoplasm. The passage of small clots induces a renal colic simulating that produced by a passing stone.

The tumor is usually bilateral and is generally discovered in the course of a routine physical examination or in some instances by the patient. In obese individual or where these masses are just slightly enlarged their palpation is accomplished with great difficulty or not at all. These enlarged kidneys are hard, irregular, and even nodular. They are tender in the presence of an infection.

These earlier manifestations of a renal lesion are succeeded by a train of general symptoms,

such as headache, nausea and vomiting, indicative of a progressive renal insufficiency terminating in coma and death, in which manner most of these patients expire. Four of the patients reported here made such exodus. Still reports 26 cases, all terminating after a state of uremic coma.

The urine, which is identical to that found in interstitial nephritis, shows a large output in twenty-four hours, except prior to death, when it is much diminished. Varying amounts of albumin are present. Casts are not a constant finding. Blood and pus are found in about one third of cases.

From a study of the above cases, two stages may be observed clinically. 1. Tumor, 2. nephritis.

In the tumor stages, these patients may be cognizant of the presence of a mass in the abdomen and are not at all incapacitated from their usual duties. If the kidneys are very much enlarged, then they are apt to complain of a sense of pressure in the abdomen. The urine at this time shows very slight, if any, changes. There is no retention of nitrogenous material in the blood, and the blood pressure is normal or just a little above. This stage may last indefinitely before kidney destruction advances to the stage where the kidneys fail to function. One of our patients, Case vi, was known to have two large tumors (kidneys) for four years before she showed evidence of a failing kidney. Another, Case iv, who had two large kidneys apparently for a great length of time, would have undoubtedly lived indefinitely but for the post-operative complication.

In the second or nephritic phase, there is all evidence of a kidney insufficiency. They generally complain of headache, nausea and vomiting. There is already nitrogenous retention in the blood and an increase in blood pressure. From this point on this disturbance in renal function is progressive and in a very short time uremic coma supervenes terminating in death. One of our patients, S. N. lived for three years after the discovery of an interstitial nephritis, with apparent comfort.

PATHOLOGY

Both kidneys being usually involved vary in size from normal to several times the normal. They are irregular and studded with cysts ranging in size from a pinhead to a grape fruit. If the cysts are uniform in size, there is some resemblance to a bunch of grapes. The color of each cyst varies depending upon its contents. The capsule is very thin and adherent and may form the wall of some of the surface cysts. On cross section, the kidney has the appearance of a honeycomb. The cysts, some of which have coalesced, are separated by fibrous septa and compressed kidney tissue. The fluid in the cysts

is either clear, yellow, and acid, holding in solution the urinary salts, or may be turbid and brown, containing pus, blood, uric acid, crystals and cholesterol. The pelvis is generally the seat of congestion and punctate hemorrhages. Hydro-nephrosis is also not infrequently found.

Microscopic section shows large irregular spaces (cysts), with a fibrous wall varying in thickness, lined with a single layer of flat or polygonal cells. In some, the cells have entirely disappeared, owing to the prolonged pressure within the cyst. Between these cysts there are areas of connective tissue in which are to be seen the remains of the previously functioning kidney tissue. The glomeruli and tubules show marked atrophic changes, with a replacement fibrosis, the end result of the pressure atrophy. There is also a round cell infiltration and arterial thickening. In the earlier cases, where death was caused by some intercurrent disease, apparently normal kidney tissue or with slight productive changes is to be seen. Other congenital malformations, such as cortical adenoma and islands of cartilage, have been described by some observers.

Cysts have been not infrequently found in other organs, the liver being the most frequent site. The ovary, choroid plexus, pancreas, epididymis, bladder, ureter and thyroid are other organs in which they have been noted. Some of the earlier pathologists and exponents of the neoplastic theory presented such findings as evidence of metastasis from the cystic kidneys which they regarded as malignant. Anomalies, such as hair lip, cleft palate, club foot and supernumerary toes have also been observed.

DIAGNOSIS

The presence of bilateral tumors corresponding to the kidney region, a hypertension and signs of a nephritis should be regarded as pathognomonic for polycystic disease of the kidneys. If a unilateral mass is found on examination, although both kidneys may be affected, it might not unnaturally suggest some erroneous diagnosis. The lesions most commonly mistaken for polycystic kidneys are hydronephrosis, pyonephrosis, neoplasm, less often renal lithiasis, T. B. C. and nephritis.

Since the advent of the cystoscope and pyelography, the diagnosis has been established with greater ease. Very often, a definite diagnosis is impossible and only an exploratory or post mortem examination will reveal the true nature of the condition.

PROGNOSIS AND TREATMENT

The condition is very grave, for after the appearance of kidney insufficiency their decline is rapid. It is already a warning that the reserve power of the kidney has been exhausted. In a practical sense, polycystic kidneys with symptoms

may be regarded as a case of advanced malignancy, so that we must resort to palliative measures for relief.

Patients possessing polycystic kidneys without symptoms should be left alone, for their existence may be quite comfortable for many years. However, they must be warned of the seriousness of this lesion, so as to impress upon them the care which must be exercised against adding any unnecessary injury to potentially diseased kidneys. Repeated pregnancies must be advised against, as it undoubtedly shortens the life of our female patients. When there is clinical evidence of a disturbed kidney function, then all efforts must be directed towards aiding elimination as is practiced in the usual nephritides. It is during this stage that some surgeons advocate operative intervention, despite the high mortality. Watson reports a case of polycystic kidneys in whom the symptoms pointed to one kidney which contained several suppurating cysts, thrombosis of the renal vein, with gangrene of the kidney. A nephrectomy caused the patient's survival for six and a half years. He claims that if one kidney is badly damaged as to imperil immediate life, and if the other kidney is reasonably functional, then a nephrectomy may be done.

Rovsing describes several cases in whom he exposed the kidneys to puncture the cysts, thereby releasing the pressure on the remaining kidney substance and prevent it from undergoing further pressure atrophy. The patients showed remarkable improvement, urinary excretion reappeared to a striking degree, pressure symptoms had subsided, in general, such satisfactory results accrued from this procedure that it prolonged life from two to three years.

Payr reports a similar experience and considers a nephrectomy justifiable only in cases of severe and persistent hemorrhage. In a certain class of cases where there is repeated colic, pain and slight hemorrhage, he advises puncturing of all accessible cysts after exposing the kidneys with a small pointed galvanocautery. Such procedure is harmless and temporarily ameliorates the symptoms. Infection of either kidney with threatening sepsis, as in one of the cases reported here, makes operative intervention imperative.

CONCLUSIONS

- 1 Although there is no conclusive proof as to the etiology of this lesion, yet all evidence seems to be in favor of the congenital theory.
- 2 The condition is generally bilateral and more common in females.
- 3 Several members of one family may be affected.
- 4 The largest proportion of cases is seen in the terminal or nephritic stage, with pronounced signs and symptoms of a chronic nephritis.
- 5 Operative intervention, although accompanied by a high mortality, is indicated in a very small number of cases where there is persistent severe pain and hemorrhage or where sepsis imperils the immediate life of the patient.

SHORTENED HOSPITALIZATION FOR DIABETIC PATIENTS

By H N COOPER, M D,
WATERTOWN NEW YORK

DIABETES is preeminently an economic problem to its victims. The disease has a life long attachment. These patients must be more or less continually under the supervision of a physician. The financial loss, in terms of medical charges and loss of earning throughout the various periods of invalidism, probably total as much or more as any other disease. The attending physician's duty is to recognize this and to cooperate in minimizing this feature.

Diabetes is a disease that should be cared for by the general practitioner. As pointed out recently by Haven Emerson, it is increasing rapidly in its incidence. As a cause of death despite the use of insulin, it is also increasing. If this present rate of increase is maintained for ten years more, it will rank with cancer and tuberculosis as a cause of death. This startling fact means that to prevent fatal outcome of the disease, the family doctor must assume the relatively simple but intelligent control of his patients. He must also seize every opportunity to lessen the economic loss the patient encounters.

The treatment of diabetes resolves itself into two phases. First the estimation of the actual ability the patient has to use sugar, or in other words his tolerance. Second maintaining the optimal diet, with or without insulin. The complication of diabetes should rather be cared for by a specialist.

As in most conditions, prompt and energetic hospitalization results in earlier return to normal and a much lessened total economic loss to the patient. The duration of the hospital stay can also be reduced to a minimum by using a standardized form of regulation. The haphazard curtailment of diet, indefinite orders to the dietitian and like methods, cause needless waste of time. Many clinics do not even waste three to four days for the preliminary desugarization of the patient. The method described below has avoided unnecessary trials and tests to a mini-

mum and the results obtained are the same as with the older methods. In other words, we want to find out how much sugar the patient can metabolize unaided, and we want him to leave the hospital on a diet which will maintain his weight and energy and keep his urine sugar free.

There is one class of diabetics to which this form of treatment is not applicable, the obese, middle-aged, mild diabetic, which is simply a case of chronic over-feeding. Moderate restrictions of the diet is all that is needed in these cases, special attention being paid to foods of high caloric value.

Immediately upon the diagnosis of diabetes mellitus, the patient is sent to the hospital. The optimal diet is estimated. By "optimal diet" is meant the amount of food required to maintain his weight and energy while doing approximately the amount of work to which he is daily exposed. For this reason, a diabetic should not be kept in bed. He should be allowed to walk so that conditions will be similar to his home environment. In suitable cases, a metabolism test should be done to accurately estimate the basal caloric needs. To this is added 30 per cent for a patient leading a sedentary life and 60-80 per cent to one engaged in active physical exertions.

The maintenance or basal needs can also be figured from the following tables. The height and weight is measured. From this his body surface area is obtained by means of the DuBois Surface Area chart (chart I). Then the standard rate is taken from the Aub-DuBois chart (chart II). For this the age and sex is needed. The standard rate times the surface area gives the hourly need and times 24 gives the daily need. To this figure is added 30 per cent for physical work.

Example Man, 24 years 67" x 134 lbs. Surface area is 17 sq meters. Standard basal metabolism 39.5 calories per hour per sq meter. $39.5 \times 17 \times 24 = 1611$ cal in 24 hours. $1611 + 483$ (30% of 1,611) = 2,094 calories to be given in 24 hours.

To obtain the correct partition for the constituents we make use of the following

Overweight subjects $\frac{1}{2\frac{1}{2}}$ gm CH per Kg of body weight
 $\frac{2}{2}$ gm " " " " " "

Normal or underweight $\frac{1}{2\frac{1}{2}}$ gm CH per Kg of body weight
 $\frac{2\frac{1}{2}}$ gm " " " " " "
 $\frac{1}{1}$ gm " " " " " "

$$37 \times \begin{matrix} \text{or} \\ \text{urine N} = 32 \text{ gms} \\ 10\% \text{ F} = 19 \end{matrix} = 140 \text{ gms}$$

140 total glucose intake

$$\begin{array}{r} \text{Total Output} \\ 24 \text{ hours urine} \quad 2000 \text{ cc} \\ \text{glucose} \quad \quad \quad 2\% \\ \hline 40 \text{ gms} \end{array}$$

40 gms output

100 gms of tolerance

A diet based on these figures is a basal diet and there is still need for more calories. These should be added only in the form of glucose and fat. As long as the amount of fatty acids is less than 1.5 times the total glucose, there is no danger from acidosis. Hence, in adding sugar and fats, the ratio of 1 gm of carbohydrate to 1.5 gm fat should be observed. Most recent work indicates that fat may be added in excess of this but this is a conservative ratio. The remaining calories then will be supplied by adding carbohydrate and fat in their ratio. A convenient method of finding the grams of carbohydrate is to divide the needed number of calories by 17, which gives the grams of carbohydrate. The amount of fat will be 1.5 times this.

Example: Normal weight subject 60 Kg as in the above example, CH 60, P 60, F 150. The total calories are $(4 \times 60) + (4 \times 60) + (9 \times 150) = 1590$. His optimal diet consists of 2094 cal. Hence, we must supply $2094 - 1590 = 504$ cal in the form of CH and fat. $504 \div 17 = 29$ gm of CH. $F = 29 \times 1.5 = 43.5$. Thus the total optimal diet is CH 89 P 60 F 193.5. This yields 2094 calories.

With the optimal diet figured, the patient is placed immediately on this food list. No insulin is given. Twenty-four hour samples of urine are examined quantitatively for sugar. This continues for four days with a blood sugar estimation during this period. The output of sugar daily should show a rather close agreement. This output is subtracted from the total intake to estimate the tolerance. The total glucose is represented by the sum of the sugar producing foods. This is 100 per cent of the CH, 58 per cent of the protein and 10 per cent of the fat. These figures represent the proportion of each food stuff, that is transformed into sugar, during its assimilation. In this laboratory, the actual total CH intake is estimated as follows: 100 per cent of the CH, plus 10 per cent of the fat, plus the estimated sugar derived from the protein metabolized. The amount obtained from the protein in many underweight diabetics is not 58 per cent of the protein. In many cases the nitrogen balance is disturbed and their own body protein may be burned or the administered protein stored to replace a deficiency. The actual amount of catabolism of protein into sugar is found, as done by Wilder of the Mayo Clinic, by multiplying the total 24 hours urinary nitrogen by the factor 3.7.

Example: Total intake of glucose, in the above case
 100% CH = 89 gms
 58% P =

This gives, in four days, the actual ability of the body to utilize sugar at that time. If no sugar is present in the urine, the patient continues on this diet and, of course, does not need insulin. At intervals, after the patient leaves the hospital, 5 grams of carbohydrate and 10 grams of fat are added to the diet, if more nourishment is needed.

If there is glycosuria on this optimal diet insulin should be given to supply the body's deficiency in this hormone. The amount of insulin needed is roughly indicated by $\frac{1}{2}$ the grams of eliminated sugar. One unit of insulin (on the average) will cause the body to metabolize 2 grams of CH. If ten units or less are needed it is given in one dose in the morning before breakfast. Ten to twenty units are divided into two equal doses and over twenty into three doses before each meal. In general, a balance with insulin will be obtained in three to four days. This can be proved by a blood sugar test. If after three days the blood sugar is still high or there is glycosuria, the insulin should be increased.

A resume of the plan is

(1) Estimate the optimal diet either by a metabolism test or by his body surface area and the Standard Basal values from the charts adding whatever is necessary for the production of physical energy.

(2) Four days on this diet, measuring output of sugar if any. If there is no glycosuria, insulin is not needed and the patient is discharged to continue on this diet. If sugar is present in the urine, give one-half as many units of insulin as grams of sugar in the twenty-four hours specimen. A level will be reached in three to five days with minor variations in the dosage. During the stay in the hospital the patient has seen the proper diets as prepared by a trained dietitian. He has been taught how to administer to himself the insulin as well as how to test the urine for sugar. The follow-up treatment is obvious—to reduce the amount of insulin used at frequent intervals, keeping the urine sugar free.

It is felt that a briefer hospitalization is possible for the average diabetic. The method here outlined gives all the necessary data in the control of such a case, providing acidosis or other complications are not present. Accurate and

energetic treatment at the inception of the disease results in much less loss of time and is more economical. Diabetes is increasing in incidence and naturally falls to the care of the family doctor. He is the one to have permanent supervision of the patient.

BOTULISM—CASE REPORT WITH CLINICAL AND LABORATORY INVESTIGATIONS * †

ALVIN G FOORD, M.D., and ANNA E FORSYTH, M.D.

BUFFALO

Numerous references on botulism are available in recent literature, especially the monographs of Dickson¹ and Bengston² and articles by Thom et al³, and Burke⁴, and to these the reader is referred for a complete bibliography of the subject of botulism.

The case herein described is that of a white widow, aged 46, dying from botulism five days after eating spoiled home-canned string beans. These had been canned in a "Sealtight" jar by the "cold pack method," and kept at room temperature for six months. The patient ate one tablespoonful at noon on January 18, 1925, but on account of the pungent, very disagreeable odor and taste took no more. A mouthful of beans was tasted by the patient's daughter who promptly spat them out. She developed no symptoms. About 9 a. m., 20 hours later, the mother complained of general malaise and nausea, followed by vomiting by 3 p. m., which persisted until evening. The following morning, January 20, difficulty in swallowing, articulation, and moving the tongue developed, followed in about two hours by a ptosis of both eyelids, moderate dizziness and a feeling of a choking sensation in the throat, which culminated in an acute attack of dyspnoea with fear of strangulation. The choking sensation led to the calling of a physician who found no organic basis for the same on examination of the mouth and throat.

The symptoms became more severe, especially the choking sensation and dyspnoea. Diplopia from external strabismus of both eyes developed on the third day. By the evening of

the fourth day the patient was comatose and breathing with difficulty. She was admitted to the hospital at 7 p. m. No history was available at that time, most of the above facts being obtained after death from the daughter.

Physical examination on admission showed dilated pupils, inactive to light, bilateral external strabismus and ptosis, muscular reflexes all inactive and the muscles flaccid. Temperature was 99, pulse 90, respiration 20, blood pressure 110-70. The heart, lungs and abdomen were negative.

Marked constipation persisted throughout the course of the disease. The temperature remained below 99 until the day of death, then rising to 101 degrees. The urine showed a trace of albumen and a few hyalin casts. Wasserman test was negative, blood urea nitrogen 22.4 mg and blood sugar 0.135 per cent. Death occurred 22 hours after admission, and five days after eating the spoiled beans. The only clinical diagnosis mentioned during life was that of possible neurosyphilis, based chiefly on the cranial nerve symptoms. However, the diagnosis of botulism was entertained at the autopsy table when the full history was obtained.

The autopsy performed by Dr William F Jacobs showed both grossly and microscopically a marked passive hyperemia of all the thoracic and abdominal viscera with small areas of hemorrhage in the lungs. The brain showed a moderate edema and a profound hyperemia, quite generalized, but most marked at the base, the small vessels standing out prominently after section of the wet brain substance. Microscopically, an occasional ante-mortem thrombus was seen in the small ves-

* Read at the meeting of the New York State Association of Public Health Laboratories at Syracuse, May 13, 1925.

† From the Laboratory of the Buffalo City Hospital.

sels with an occasional small area of hemorrhage around the same, besides a marked distension of all the capillaries with blood. No thrombi were found in the meningeal vessels and no distinct changes were seen in the cells of the brain. Parenchymatous degeneration and albuminuria were present in the kidney tubules. The liver showed some small droplets of fat in the peripheral cells of the lobules and a yellow punctate pigment deposit in the hepatic cells around the bile capillaries, apparently bile pigment. The stomach and intestines showed no evidence of irritant poison, but merely shared in the general congestion of all the viscera.

Injection intraperitoneally of 1-1000 cc salt solution extract of the beans, which were obtained from the garbage (wrapped in paper and frozen stiff for five days), produced death in guinea pigs in less than 24 hours. Two chickens were highly refractory to 6000 times this dose by mouth. Pure cultures from the beans, and from the intestinal content of the patient obtained at autopsy, were grown by planting the extract and feces, heated to 80 degrees for 10 minutes, into one per cent dextrose agar neutral to phenolphthalein, one per cent dextrose broth (pH 7.0), blood agar plates, and into brain emulsion made by mixing equal portions of the macerated sheep brain and distilled water, filtering through gauze and autoclaving. To a few tubes of the latter a small piece of sterile rabbit kidney was added, which seemed to enhance the growth. The cultures were grown in both daylight and dark at room temperature for ten days to two weeks under anaerobic conditions in a Novy Jar, and a large bottle combining the hydrogen with the pyrogallic acid and sodium hydrate method. Both straight rod forms and drumstick spore-bearing types of the organisms were found in the beans as well as in all subcultures. Cultures liquified gelatin, clotted and later digested the casein in litmus milk with acid production, and produced acid and gas in dextrose, maltose and mannite, and slight acid in lactose.

Toxin was slightly stronger in cultures grown in the dark, the average fatal dose for guinea pigs being about 1-1000 cc. The symptoms and pathological findings in all the animals were typical of botulism, with marked hyperemia of all the organs, especially the brain, occasional thrombus in the small vessels

and a distension of the stomach, which characteristically tore easily on handling. The thrombi were found in only three animals. Guinea pigs, of which 33 were used, were relatively a little more sensitive to the toxin than the four rabbits injected. Chickens were highly refractory, 9000 lethal doses for guinea pigs being given by mouth and 150 subcutaneously with no effect whatsoever.

Heating the original toxin (extract from beans) or that produced by culture, in a water bath at 100 degrees for five minutes entirely destroyed the same, large doses causing no effects on animals.

Guinea pigs given 3-10 cc antitoxin B (New York State Laboratory) and doses as high as 100 fatal doses of toxin remained well, while others given similar doses of toxin plus 3-10 cc antitoxin A, or toxin alone, died promptly with typical clinical and pathological findings of botulism. The results were the same with the toxin produced from the culture obtained from the beans and that from the intestinal content of the patient at autopsy.

Summary

A case of botulism, fatal in five days, due to eating home canned string beans, is presented.

Bacillus botulinus, Type B, was recovered in pure culture from the spoiled beans, and from the intestinal content of the patient at autopsy.

Toxin production by the organism was vigorous. Chickens were immune to enormous doses of the same, whereas guinea pigs and rabbits were highly susceptible. Heating the toxin in boiling water for five minutes destroyed it completely.

Pathologic findings were characteristic of botulism in the patient as well as in the animals.

INTIMATIONS OF PUBLIC HEALTH IN EARLY NEW YORK *

By DONALD B. ARMSTRONG, M.D. Sc.D.,

NEW YORK CITY

MAY I first call your attention to an ordinance passed in New York City (then New Amsterdam) about the middle of the Seventeenth Century, dealing with street safety and hygiene. It reads as follows:

"As the roads and streets of this city are by the constant rooting of the hogs made unfit for driving over in wagons and carts, the Board directs and orders that every owner of hogs in or about the city, shall put a ring through the nose of their hogs to prevent them from rooting, within eight days, under a penalty of two florins for each time that this ordinance is not obeyed, and that it may be properly carried out, we charge and direct hereby, our officer to see to it and provide against transgressors after the publication hereof. This done at the City Hall, August 19, 1658."

While the cause of torn-up streets was rooting hogs and not "sand hogs," yet the sentiment has a familiar modern sound, not entirely foreign to Twentieth Century complaints.

Indeed, a study of early colonial life from the public health point of view encourages two paradoxical and somewhat contradictory impressions. In the first place, the incipient movements for health conservation and for public comfort and safety seem so inadequate and remote when compared with the modern scale as to bear little relation to the intricate and relatively magnificent measures of the current social order. On the other hand, one gathers the impression that there is "nothing new under the sun." There appears to be a striking similarity in problems, devices, and (alas in some instances) results.

The records of early New York during both the Dutch and English occupation, up through the first half of the Nineteenth Century, reflect the sanitary and hygienic problems of which the community and its leaders were conscious. One finds certain measures of personal hygiene and certain initial provisions for the control of medical service, including certain beginnings at the socialization of medicine. There is an early recognition of the need for sanitary regulation, for city planning, and for organized efforts to meet collectively such requirements as proved to be beyond the range of individual capacity. The findings are fragmentary, yet symbolic and indicative of the trend of the times—the pre-natal period of the sanitary awakening to follow.

A few examples of early health provisions may be cited.

Very early recognition was given to the need for some sort of official control over the prac-

tice of medicine. It was characteristic of a primitive condition that for a time a greater degree of official supervision existed than prevails ordinarily in most mature communities. In 1652, there occurred in New Amsterdam, the earliest local order on record regulating the practice of medicine (and incidentally indicating the metamorphosis of medicine out of barbering). To quote the New Netherland Register for February, 1652:

"On the petition of the chirurgions of New Amsterdam that none but they alone be allowed to shave, the Director General understands that shaving doth not appertain exclusively to chirurgy, but is an appendix thereunto, that no man can be prevented operating on himself, nor to do to another this friendly act, providing it be through courtesy, and not for gain, which is hereby forbidden. It was then further ordered that ship barbers shall not be allowed to dress any wounds nor administer any potions on shore without the previous knowledge and special consent of the petitioners."

This is undoubtedly the earliest official effort to regulate the practice of medicine, and incidentally reminds us of our humble origin. The Netherland Register further states:

"The first members of the medical profession in New Netherland were, of course, ship surgeons who practiced on shore while their vessels lay in port. Some of them settled at the Mannhattans, and worked out a subsistence by being sometimes employed by the Government."

Of this period Mrs. John King VanRensselaer wrote:

"A midwife by the name Maryje Jans was sent to the Colony, and also two men by name Sebastien Jansen Crol, and Jan Huyck, sick men's comforters, who were ordered to nurse and doctor the injured, and also conduct prayer meetings, read the Bible, and look after the welfare and morals of the community." Also Sylvant Sornelesli was appointed Assistant Surgeon "to be employed in shaving, bleeding and administering medicine to the soldiers."

Finally, indicating the extent of community control, an ordinance of 1656 may be quoted:

"The barbers, whether on board a ship or on land, shall be bound to give their services cheerfully, and to use all diligence to restore the patients to health, without receiving therefore any compensation except their monthly pay, and, in case any of them receive any money or promise of payment, they shall be obliged to restore what they receive and the promise shall be null and void."

* Presented before the New York Academy of Medicine (Historical Section) February 25, 1926.

The practice of midwifery was also not neglected. States the *New England Register*:

"Midwives in Holland, before being licensed were duly examined by a board of physicians. One of such licensed women was appointed midwife to a town or village. This custom was transferred to New Netherland."

There is also on record an order allowing Hellegond Jons, a midwife, a salary of 100 guilders (\$40) a year for attending the poor. Whether she was considered overpaid or not, the record does not state. The record does indicate, to quote again, that "as early as 1658, a hospital was provided in a clearing, with fires of wood, and a nurse was engaged to look after the sick." The exact location of that institution is apparently uncertain.

One finds scattered throughout the records of the Dutch colony, numerous references to organized dealing with health and sanitation, or with subjects assumed at that time to bear a relation to the health of the community. These deal with the inspection of meat, water supply, street cleaning, drains, and ill smelling cheese. Hogs were apparently a perpetual nuisance. To quote again the records of New Amsterdam:

"Officer Pieter Tonneman wishes to know, whereas some dead hogs lie here and there on the street, where he shall have them conveyed and by whom, to prevent the stench which proceeds therefrom. He was notified to send the city's negroes whom he shall order to collect and bury the same. Tuesday, April 8, 1664."

Thus we note a problem which Mayor Walker and his Street Cleaning Department are fortunately spared.

The problem of rubbish and dead animals existed then as now.

"It has been found that within this City of Amsterdam, many burghers and inhabitants throw their rubbish, filth, ashes, dead animals and suchlike into the public streets to the great inconvenience of the community and dangers arising from it. Therefore the burgomasters ordain and direct that henceforth no one shall be allowed to throw into the streets or into the canal, any rubbish, filth, ashes, oyster shells, dead animals, or anything like it, but they shall bring all such things to the most convenient of the following places, to wit, the Strand, near the City Hall, near the gallows, near Hendrick, the Baker, where tokens to that effect shall be displayed, but not on the public streets, under a penalty of three florins for the first offense, six florins for the second, and arbitrary punishment for the third."

Apparently, this and subsequent ordinances had little effect, for the patrolmen today, at certain hours of the early morning, still walk close to the building line in order to avoid a possible shower from above, and still today the work of nuisance abatement and of the removal of dead

animals constitutes an illegitimate phase of the program and budget of the average town and city health department. The reference to oyster shells is also of interest for it indicates dietary progress from an earlier period in New Amsterdam, concerning which it is stated elsewhere that owing to an extremely hard winter, attacks by the Indians, a poor crop, and lack of shipments from abroad, the inhabitants of New Amsterdam were so hard pressed and sunk so low as to find it necessary to eat oysters!

Privies existed and were a problem then as now. It is still true that probably a third of our urban population in this country is unsewered. While there is no record of a hookworm menace, yet we find the following provision:

"Whereas many, even the greatest part of the burghers and inhabitants of this city, build their privies even with the ground, with an opening toward the street, so that hogs may consume the filth and wallow in it, which not only creates a great stench and further great inconvenience to the passersby, but also makes the streets foul and unfit for use—therefore to obviate, the Burgomasters herewith order and command that all and everybody, whoever they or he may be, shall break down and remove such privies coming out upon the street, within eight days after the publication hereto, rebuilding them in such places that they give the least offense to the community under the penalty of six florins for the first time, double as much for the second, and arbitrary correction for the third."

The first record of a public water supply occurs in 1658 when the Burgomasters resolved to look into the question of having a public well made in Heere Street. It is stated that the first British provision for a public water supply was made at the time of Aaron Burr, and under his auspices, when he secured the passage of a bill permitting him to dig a well in Catherine Street, and establish a water company. It is also stated that this legislation permitted him to do as he saw fit with the excess appropriation or proceeds from the venture, and that he established a bank as an adjunct to the well. It is not inconceivable that here may have originated the term "stock watering."

In these early days, industrial hygiene was not altogether neglected, or at least, hazards of industry as they might affect surrounding neighborhoods. To quote again the records of New Amsterdam:

"William Van der Borden and Daniel Verveelen appearing, represent that a tannery was established between their house and lots, and as they fear their water shall be thereby spoiled and they shall also have to endure great stench from the tanning of skins, they request that such be forbidden, especially the digging of a pit in which the skins are soaked. The Burgomasters

decreed that as others have been allowed to make a tannery between their house and lot, such cannot be forbidden Tuesday, July 8, 1664"

We have referred to the street hazards created by the rooting hogs. It is also evident that New Amsterdam had a traffic problem. Among the laws and ordinances we find

"The Director Generals, in order to prevent accidents do hereby ordain that no wagons, carts or sleighs shall be run, rode, or driven at a gallop within this city of New Amsterdam, that the drivers and conductors of all wagons, carts and sleighs within this city shall not sit or stand on them, but now henceforth, within this city (the broad highway alone excepted) shall walk by the wagons, carts, or sleighs, and shall take and lead the horses on the penalty of two pounds flemish for the first time, etc."

Again, on the question of safety, our press today is not altogether devoid of recommendations made by the Police Department, by judges, and others, concerning the careless use of firearms. Apparently the first "Sullivan Law" to be adopted on this Island was in 1652 which read in part as follows

"Whereas many guns are daily discharged and fired at partridges and other game within the jurisdiction of the city, and in the vicinity of the fort, by which firing people or cattle might perhaps be struck and injured, against which practice complaints have already been made, therefore the Honorable Director General in order to prevent accidents, expressly forbids and interdicts all persons henceforward firing within the jurisdiction of this city"

This is perhaps a little bit removed from the question of health and disease, but I intend to wander just one step further before closing these citations. Is the liquor question a health problem? If it is now, then presumably, it was also a health question in the Seventeenth Century. At any rate, the problem, however it may be classified, was recognized, and met by legislative and educational efforts strangely similar to modern volsteadian procedure, with not dissimilar results so far as one can judge. We must go back to 1638 for the preamble to an ordinance which you may find of interest

"Whereas the Honorable Director William Kieft and Council of New Netherland have observed that much mischief and perversity is daily occasioned by immoderate drinking, therefore the said Honorable Director General wishing to provide against the same, has interdicted and forbidden, does hereby interdict and forbid, all persons from now henceforth selling any wine on pain of forfeiting five and twenty guilders, and the wines which will be found in their houses, except only the store where wine can be procured at a fair price and where it will be issued in moderate quantity"

Evidently an early experiment with the Quebec system!

The ordinance proceeds

Whereas we see and experience that our former edict enacted against unreasonable drinking to excess both at night and on the Sabbath of the Lord, to the scandal and shame of us and our nation, is not observed and obeyed according to our intent and meaning, we hereby renew the same and do ordain and enact that it shall henceforth be put, maintained, and executed in strict observance and force, pursuant to the time and provision therein set forth. Meanwhile, the reason and cause why this one good edict and well meant ordinance is not obeyed according to the tenor and purport thereof, are that this sort of business and the profit easily accruing therefrom, direct and lead many from their original and primitive calling, occupation and business, to resort to tavern keeping so that nearly the fourth of the city of New Amsterdam consists of brandy shops, tobacco and beer houses by the multitude whereof not only more honorable trades and occupations are neglected and disregarded, but even the common people and the city's servants seriously debauched, and what is still worse, the youth seeing and following as from their very childhood, this improper example of their parents, are drawn from the path of virtue and into all sorts of irregularities. Hence also proceed cheating, smuggling, and frauds, and the clandestine sale of beer and brandy to the Indians and natives, as daily experience, God Help Us! shows, from which nothing but new difficulties between us and them ought to be apprehended, and moreover, decent taverns, established and licensed for the use and accommodation of travellers, strangers, and inhabitants which honestly pay their taxes and excise, and hold or lease suitable houses, sitting under heavier expenses, are seriously injured in their licensed and lawful business by these underground grogeries"

There then follow provisions forbidding a new tavern to be set up without permission, and regulating existing ones. Later, after this regulative and suppressive ordinance had been passed, and presumably enforced, after the manner of its kind, we find a reference in 1648 which reads as follows

"We do hereby interdict and forbid all persons on the aforesaid day (the Sabbath), spending his time to the shame and scandal of others, in gross drunkenness and excess on pain, being so found, of being arrested by our fiscal, and senior, and inferior officer, and arbitrarily punished by the Court"

That was in 1648. Then here is another quotation from the lips of a famous Bishop of the Episcopalian Church taken from the *New York Times* of February 8, 1926

"I, have come to the conclusion that the Volstead Act has resulted in worse drinking conditions among people than we had before, that it has increased enormously among them the use of strong distilled liquors, often poisonous and dangerous, that it has corrupted officials, has brought about an increased disrespect for law

Now we are in danger of relying on legislation to enforce sobriety, with the result that evasion of the law is regarded as a clever joke to be applauded rather than a crime to be condemned. Nobody wants the oldtime saloon back again, but many people dislike and hate the bootlegging substitute."

These comments of the New Netherland City Fathers have a peculiarly modern sound. They had their "underground grogeries," their bootleg problem, and the youth were being debauched as usual. History repeats itself, and we are usually blind to our previous experience. Could we perhaps have learned something from the experience of New Amsterdam? At any rate, it is too late now for we are launched on our own legislative experiment, and will have to go through with it. The outcome of this earlier experiment is not clear. Current Prohibition advocates assure us that it will take several generations to establish the full benefits of our recent Constitutional amendment. Do subsequent records throw light on the sequelae of these earlier efforts at control? It is hard to say, but if we consult the later mortality records of New York City, rather interesting findings are disclosed. There is in existence, a semi-centennial table of mortality, I believe the first available mortality records for the city, presenting the causes of death from 1804 to 1853. In this are found, among other things, certain peculiar differences from what we now know as the International List of Causes of Death. For instance, by 1805, there were 11 deaths from "Drinking Cold Water." By 1825, this factor in our mortality had reached the epidemic proportions of 77 deaths. In spite of the mortality, apparently the blue ribbon movement was rampant. What, however, are we to think of the subsequent backsliding and period of decadence shown by 119 deaths in 1831, for which the cause was certified as "intemperance," with 137 deaths from delirium tremens in 1847, and 128 deaths from the same cause in 1853. In 1826, following the cold water epidemic of 1825, when the population of the city was approximately 160,000, there were 6 citizens of New York killed and murdered, 13 died from sudden death by violence, 29 by suicide, and 63 by drowning. You may draw your own conclusions as to what is in store for our grandchildren!

You will be interested perhaps in certain additional facts disclosed by these early mortality tables. There are many curious reflections, not only of the death certification procedure of the

times, but of the prevailing sanitary conditions of the city. A few of the rather odd causes of death may be cited. In 1847, there was one death from rattlesnake bite, in 1846, three deaths from salivation, 1853, one death from piles, and also one death from obesity, in 1842, ten deaths from constipation, in 1853, one death from swinepox, in 1837, one death from "furor of the womb", and for the period 1807-53, 49 deaths from mensesmenstruation.

On the other hand, in 1805 there was recorded only one death from diabetes and there were very few more than this for many years. Other records reflect the terrible conditions that prevailed in New York City at the beginning of the Nineteenth Century, the extreme degrees of insanitation, bad housing, overcrowding, incompetent administration, filth and ignorance. In 1853, there were 13 deaths from scurvy, in 1851, when the city had a population of 538,400, there were 977 deaths from typhus fever, or a rate of 181.5 per 100,000. In 1805, with a population of 78,429, there were 270 deaths from yellow fever, or 344.3 per 100,000. As late as 1822, the yellow fever rate was 119.9 per 100,000. The big year for cholera was 1832, with 3,513 deaths, or 1,558 per hundred thousand, against a population of 225,000. Smallpox continued intermittently to be a serious factor. In 1804, there were 169 deaths, or 226 per 100,000, in 1824, 394 deaths, or 257 per 100,000. As late as 1853, there were 656 deaths, or 112 per 100,000. While in 1924, the smallpox death rate for New York City was zero, the disease of course constitutes a danger not yet removed owing to laxity in vaccination procedure—first introduced in New York by a Dr. Seaman in 1801. While there has been of late little of the disease in New York City itself, it has been prevalent in many surrounding communities, and the figures for the incidence of the disease in the United States as a whole are a disgrace. In 1924, we had the largest number of cases of any country in the world, except British India, but not excepting Russia.

The old records are not especially adequate on the questions of maternity and infancy. Deaths in 1804, incidental to the puerperal state, numbered 16, or a rate of 21.4 per 100,000. Unfortunately, this is not in striking contrast to the rate of 11.3 per 100,000 for 1924. There were no infant mortality rates for the older period, of course, for birth registration either did not exist or was, at any rate, largely neglected. We find, however, that in 1804, there were 33 deaths from "teething," rising to 242 in 1837. The centennial table does show the number of deaths for one year or under, and these can be compared with current figures. In 1804, there were 428 deaths, or 571.9 per 100,000 population. In 1825 the rate was 538. In

1853, the rate was 992, as compared with a rate of 146.6 in 1924

Diphtheria or Croup was, of course, a considerable factor in mortality, showing a rate of 122 per 100,000 in 1806, 96 in 1831, 115 in 1853, as compared with 11.9 per 1924 Typhoid fever, if one credits the diagnoses with any degree of authenticity, showed a rate of 10.4 in 1847, as compared with 3.1 in 1924 Of course, we generally admit now that any community with a rate much over 3 per 100,000 is a sanitary disgrace

Consumption played a conspicuous part as a death factor In 1804, there were 499 deaths, or a rate of 667 per 100,000 By 1832, the rate had dropped to 628 and by 1853 to 469 You are aware, perhaps, that the rate for 1925 for New York City was 88 per 100,000, which includes all forms of tuberculosis, whereas the figures cited for the previous years are those for so-called consumption only, and do not include "white swelling," "scrofula," etc

On the other hand, certain leading causes of the present day are either not prominent or unrecognized in the older records This is to be accounted for, no doubt, not only by changes in actual disease incidence, but also by differences in terminology, changes in medical knowledge, modifications in certification procedure, as well as alterations in the age composition and life duration of the population in general For instance, for cancer for the period 1804-36 inclusive, there were 355 deaths of an average of 11 a year This rose to 79 deaths in 1853, or a rate of 13.5 per 100,000, to be compared with a rate of 109 per 100,000 in 1924 As to diseases of the heart and arteries, we find in 1804 four deaths from this group of causes From 1804-14 inclusive, there were 18 deaths For the period 1815-33 inclusive, there were no deaths except those accredited to aneurism By 1853, however, there were 433 deaths with a rate of 74.1 per 100,000 The rate for 1924 was 312.5 per 100,000

The general death rates were, of course, high In 1804, the rate was 28.4 per 1,000 living By 1825, it was 31.2 In 1832, the cholera year, it jumped to 45.9 By 1853, it was 38.9, whereas last year, 1925, our general death rate was 11.49

It is evident that in the early half of the Nineteenth Century life in New York City was hazardous, short, and not particularly merry There are no life tables for New York City for that period The only data at all available are to be found in a life table constructed for certain communities in Massachusetts and New Hampshire by Dr Edward Wigglesworth for the year 1789 From this table we learn that the expectancy of life at birth at that time was 28 years At the present time, for the Registration Area of the United States, our expectancy at birth is 58 years, and we now believe that the way is clear, with the application of known hygienic knowledge, for the addition of ten or twenty years more to this average life expectancy Certainly, the contrast reflects marked changes and genuine progress, however numerous may be the factors that have brought it about

During this middle period in the history of New York City, conditions were certainly serious, and were, apparently, generally accepted There was in fact little change until the Civil War Then, striking improvements were initiated, as is often the case through the efforts of one man, the late Stephen Smith His unusual attempts at the correction of unhygienic and insanitary conditions were crowned with a high degree of success, paving the way not only for the sanitary regeneration of the city as a whole, but also for the wide stimulation of a similar movement on a national scale

Dr Smith, in his book entitled "The City That Was," published in 1911, presents a graphic description of health conditions in New York City about 1860 In his chapter on "A Blind Metropolis," he states

"New York gradually became the natural home of every variety of contagious disease, and the favorite resort of foreign pestilences Smallpox, scarlet fever, measles, diphtheria, were domestic pestilences with which the people were so familiar that they regarded them as necessary features of childhood Malarial fevers, caused by the mosquitoes bred in the marshes, which were perfect culture-beds, were regularly announced in the autumnal months as having appeared with their 'usual severity' The 'White Plague,' or consumption, was the common inheritance of the poor and rich alike

"With the immigrant, came typhus and typhoid fevers which resistlessly swept through the tenement houses, decimating the poverty-stricken tenants At intervals, the great oriental plague, Asiatic cholera, swooped down upon the city with fatal energy, and gathered its enormous harvest of dead Even 'Yellow Fever,' the great

pestilence of the tropics, made occasional incursions and found a most congenial field for its operation."

Later Dr. Smith makes a housing reference which is not altogether atypical of reports of a much more recent date.

"Very few tenements have waterclosets in the houses, they have privies in the yards, which, as a rule, are insufficient for the accommodation of the numbers crowded into the houses, many are not connected with the sewers, are seldom cleaned, being allowed to overflow in some cases, rendering the neighborhood offensive with insalubrious emanations."

In a summary of disease conditions by wards of the city during the year 1864, he comments briefly upon the Eighth Ward as follows:

"The prevailing diseases of the past season have been fevers of the typhus, typhoid, remittent and intermittent types, cholera infantum, scarlatina, dysentery, and diarrhea, all confined to densely populated tenements. The typhus and typhoid fevers have been of a malignant type in two houses, twelve out of eighteen cases proving fatal."

Indicating that the city already had its apologists and "boosters at any price," Dr. Smith further states:

"And yet it is reiterated year after year by the City Inspector, that New York City, at this day, can lay claim to the privilege of being numbered with the most healthy in the world."

Keenly aware of the seriousness of the situation, Dr. Smith himself first conducted a personal survey. He reported his findings to the Police Department with the result that no action was taken. He then took the matter to the Citizens Association, organized by Peter Cooper, for the special purpose of fighting the Tweed Ring. Under the auspices of a Committee on Public Health of this Association, the first thorough sanitary survey of New York City and perhaps of any city on this continent was undertaken. You will recognize the names of many of the prominent medical men on that committee, including Dr. Valentine Mott, Dr. Joseph M. Smith, Dr. James R. Wood, Prof. John W. Draper, Dr. Willard Parker and Dr. Isaac E. Taylor.

Among other things, this survey disclosed that the city provided practically no adequate machinery for the control of disease. The sanitary work was done by a group of inspectors known as health wardens, who, according to Dr. Smith, were "generally saloon keepers." Dr. Smith relates that one of these wardens was asked to define the word "hygiene" and replied that it was "the vapor which rises from stagnant water."

This Commission drafted the first Metropolitan Health Bill in the Fall of 1864 which was introduced into the Legislature in 1865, and was

defeated. It was subsequently reintroduced in 1866, and passed in March of that year. There followed the organization of the Metropolitan Health Board which, with its far reaching and drastic provisions, and sweeping powers, laid the basis for the control of disease, and the promotion of health knowledge, in New York City and for Health Departments throughout the United States.

It is impossible in this review to touch upon the marvelous evolution of the city's water supply from the first Dutch well to the Croton and Ashokan systems, on the beginning of milk sanitation, and the extension of pasteurization, with the concomitant fall in infant mortality and tuberculosis, on the development of hospitals and clinics and organized medical service for infants, school children, and industrial workers, upon the expansion of the list of reportable diseases, or on the other great sanitary reforms and the beginnings of health education efforts with the expansion in personal hygienic instruction.

In New York City we have seen the whole cycle of modern public health development to date. Beginning with the Dark Ages of the early Eighteenth Century, illuminated by the work of Stephen Smith, leading to the shotgun methods of the sanitary policemen concerned with general environmental hazards, we have come down to the more accurate and specific attacks upon disease based on the disclosures of bacteriology. We have witnessed the development of sanitary science and specific disease control, beginning with general epidemiology and disease suppression through sanitation, and growing into a specific science of preventive immunology. We have seen it all leading up to the personal hygiene and public health education of today, first disease suppressive in character as in its earlier attacks upon tuberculosis and infant mortality, and now more largely health creative via the health examination movement and the art of health promotive habits of living.

We have witnessed a transition from the environmental to the personal, from sanitary policing to individual persuasion, from suppressive legislation to individual responsibility. In medicine, veering away from the early communism, we have noted a successive period of expansion of the private practice of medicine with a gradual return to a greater degree of group medical control for large sections of the population, such as the infants, the school children, industrial workers, and others. More recently, in medicine, we have seen on the one hand a high degree of specialization, and now on another, through the hygienic educational responsibilities of the profession, through the practice of periodic examinations, we may observe the opening up of a much larger and greater field for the gen-

eral practitioner—the private practice of preventive medicine

It is a long way from Peter Stuyvesant to Louis I Harris. Yet there is something to be learned from the study of our early experience. While history does not recur in identical cycles, and is certainly evolutionary, it is nevertheless an ascending spiral, tracing perhaps a more or less similar trajectory on the lines of which our problems, thinly disguised, have the habit of recurrence.

In public health we have the satisfaction of having more than kept pace with the growth of the city. In most respects our conditions are infinitely superior to either colonial or subsequent periods. In addition to the development in health education and the application of medical knowledge to larger groups of population, the city at the present day may as a whole, be considered well sanitated. Our methods of sewage and waste disposal are still crude, and our housing situation is perhaps an exception to this, though here both ancients and moderns are probably inclined to exaggerate the importance of unsightly

and uncomfortable conditions. We must remember that home methods are more important in disease control and health promotion than home equipment, though, of course, without certain fundamentals of equipment, satisfactory methods cannot be practiced. Ignorant, or careless human pigs in a palace will frequently have a higher sickness and death rate than clean, intelligent humans in a hovel.

Compare with other municipal interests from the point of view of keeping pace with the city's development, the workers in the public health field may be congratulated. While we are behind in our traffic problem, while we have not kept pace in the matter of food distribution, and in general in the use of mechanical invention for constructive social purposes, yet in public health we have, on the whole, gained on the situation. The evidence presented in the foregoing paper must indicate that in spite of our tremendous growth in numbers and in complexity of organization, life in New York today is safer, probably happier, and certainly longer than it was in the Manhattan of long ago.

THE TREATMENT OF LARYNGEAL TUBERCULOSIS*

By ROY S MOORE, M D
SYRACUSE, N Y

IT is the purpose of this paper to gather from the literature the opinions of men doing the most work in laryngeal-tuberculosis and to add to them my own observations made on 49 cases, which were watched and treated by me during three months of 1924 at the Hajek Clinic at the University of Vienna.

In considering the therapeutics of laryngeal-tuberculosis, the determination of the value of any one form of treatment is a most difficult one. The personal equation, the patient's temperament, the virulency of the infection, his family affairs, his financial status, his environment, all bear heavily on the outcome.

The scientific treatment may be said to have started with the advent of the laryngoscope. In the early days, most of the best men were strong in their affirmations that local treatment was of no value, and that the outcome depended entirely upon the progress of the pulmonary lesion. In 1876 M Schmidt succeeded in destroying this principle by reporting a series of cases which he thought were favorably influenced by the use of inhalations and antiseptics applied locally in the larynx, especially the inhalation of dilute carbolic acid, Peruvian bark, thymol, iodoform, creosote, sulphur, menthol, and antipyrin.

We all know that flat ulcerations can be

healed without any local treatment if the general condition of the patient remains good, by simply following out the dietetic, climatic and hygienic rules. We should not forget that we occasionally find a fibrous tubercular involvement which shows a great inclination to stay stable and become better spontaneously.

Today the therapy may be said to be divided into. First, palliative, and second, curative. Under the palliative measures may be mentioned either orthoform alone or mixed with zinc ointment, morphine in the latter stages, and the injection of the superior laryngeal nerve for the dyspnea. This procedure makes the way easier for many a sufferer. The injection should be made on one side only, waiting to see that we get no paralysis as a complication, when the other side may be injected.

The curative measures are confined to. First, surgical removal of the involved area, second, actual cautery, and third, sunlight, all, of course, combined with rest. Only such cases of tubercular inflammation of the larynx should be removed surgically as may be limited to a small area and where the involved parts are more or less pedunculated, particularly those that are located in the back wall of the larynx, the epiglottis, or in the Ventricles of Morgagni, and have not as yet involved the arytenoid cartilages. As a matter of fact, sur-

* Read at the Annual Meeting of The Medical Society of the State of New York at Syracuse May 13, 1925.

gery today is largely limited to the removal of a badly involved epiglottis, which makes the swallowing very painful and protruding granulemas of the posterior commissure which interfere with both respiration and the voice.

Many authorities feel that any type of tubercular lesion can be greatly benefited by the use of the actual cautery, the ulcers by scarring over the surface, the deeper infiltrations and tumors by repeated puncture.

In the midst of all these views, heliotherapy of the larynx, advocated by Poncet, Bernhardt and Rolier, was introduced. Lorgo in Switzerland in 1904 first applied the rays directly to the laryngeal mucosa, and since that time various methods have been advanced and used for the introduction of the sun's rays or their equivalent into the larynx. Rolier, Bernhardt and Poncet remained more or less unnoticed, although they demonstrated the fact that the sun was a healing agent. Finsen carried the work further and found in the restricted arc lamp an excellent equivalent of the sun which has become the method of treatment in Lupus.

At the various sanatoria in this country and abroad, many methods are used for introducing light into the larynx. In the sanatoria of Colorado and Arizona, where the sunlight may be depended upon day after day, Mr. Verba's laryngeal mirrors have been brought into use quite extensively. Mr. Verba was a patient himself with laryngeal-tuberculosis and being of ingenious mind, devised mirrors for the introduction of sunlight into the larynx by the patient, two mirrors being used, one fastened to some standard, as the back of a chair, the patient sitting with the sun at his back and holding a laryngeal mirror in his mouth, the light is reflected first from the mirror on the standard onto the laryngeal mirror, and secondly from the laryngeal mirror into the larynx. These mirrors are made of an alloy which reflects the greatest per cent of the ultraviolet rays. A second mirror is fastened on the standard above the reflecting mirror, in which the patient may observe the condition of his own larynx.

In our own Adirondack region, the water-cooled mercury lamp is used for the treatment of these cases. In order to get at the extent of the use of heliotherapy, I addressed a letter to various sanatoria and men interested in the treatment of laryngeal-tuberculosis, asking the following questions:

1 Do you in your sanatorium use light therapy as a routine in your treatment of any type of tuberculosis of the larynx?

2 How many patients have you exposed?

3 What types of laryngeal-tuberculosis do you consider are benefited by this treatment?

4 If you use the light treatment, what type of light do you use?

5 What methods do you employ for the direct or indirect application of the rays?

6 What have been your results?

I find that most of the smaller sanatoria such as our county sanatoria do not carry on any routine treatment for laryngeal-tuberculosis other than palliative measures. At Raybrook the superintendent informs me that their experience with light therapy is limited to relatively few cases. At the J. N. Adams Hospital at Perrysburg they have exposed about 30 cases to natural sunlight by Rolier's method of exposure and the superintendent informs me the results were good. At the Trudo Sanatorium, Saranac, they have treated from 30 to 50 cases with the ultraviolet ray, using the Burdick and Alpine lamps and general exposure only. The superintendent feels the results were good when combined with general treatment.

The work has evidently not been carried far enough to enable one to give the per cents of cure, improvement or no benefit in the various types of cases. Most authorities feel that the rays in the spectrum between the violet and ultraviolet are the ones of greatest therapeutic value. The other end of the spectrum, the red one, is the one which produces the heat and the hyperemia. These rays have a power of penetration of several centimeters. The rays from the violet end of the spectrum do not penetrate more than a fraction of a millimeter. There is, however, produced a fluorescence action and beta rays are formed which go deeper and produce a chemical action on the tissues. This biological action is proportional to the chemical power and inversely proportional to the ability of penetration.

We now know that the sunlight has an electrical destroying effect on the tubercular granulation tissue and that this action is mainly produced by the blue and ultraviolet end of the spectrum. Together with this action on the tubercular granulation tissue the light acts as a powerful stimulus for the formation of scar tissue as well as having a favorable influence on breathing, pulse, blood, etc.

In 1920 Dr. Wesley at the Hajek Clinic of the University of Vienna was entrusted by Professor Hajek because of his work in radiation with the responsibility of developing a light therapy clinic. His opinion is that the electric arc light is the best spectral imitation of sunlight, but that it is not an optimal imitation and that this imitation could be achieved only by completing the blue end of the spectrum by the addition of impregnated carbons. In Wesley's lamp the heat rays or red end of the spectra are absorbed by a water jacket introduced into the machine.

At the Hajek Clinic 50 per cent of the patients have the laryngeal mucosa exposed di-

rectly to carbon light. For this exposure the Seifert apparatus is used. In the early days the suspension apparatus was the only one available. Today the Seifert apparatus brought out by Dr Seifert of the University of Berlin, a former assistant of Professor Kilians, seems the best adapted to the work, because of the small area of pressure in the throat, viz. that of the laryngeal spatula under the epiglottis. The Haslinger Scope, because of the fulcrum on the posterior pharyngeal wall and its double area of pressure is not tolerated by the patient for a sufficient length of time to be of great service in this work.

It is the opinion of the men in this clinic that those patients who are in good condition generally and running no temperature but with marked involvement in the larynx do much better when exposed directly to the light as opposed to those treated with the reflected ray. It has been a problem to find material from which to make the indirect mirrors which would reflect any large per cent. of the beneficial rays. The ordinary indirect laryngeal mirror will throw into the larynx about 9 per cent of the rays from the ultraviolet end of the spectrum, while 95 per cent. of the light and heat rays are reflected. The mirrors used in this country are some type of alloy, varying with the clinic, while in Europe some form of steel seems most popular, the best of these reflecting only about 50 per cent of the beneficial rays.

We have then to decide whether the patient is in good enough condition to attempt to give him the best, that is, the direct exposure or whether the strain would be too much for his general condition. If we use the direct method, the throat is desensitized the same as for direct laryngoscopy or upper tracheoscopy, when the patient will lie down and the light will be thrown in for a period of from one to fifteen minutes depending upon the individual's local reaction in the throat, and the length of time that he has been under treatment. At the beginning the light is used every second day and the treatments vary from a few weeks to a year or more in length. After the termination of the actual treatment, the patient should be controlled by examination at least once each month.

The following observations were made on the 49 cases which were treated by me. First, the healthy mucous membranes stand the sun in larger doses than the skin accepts. After excessive radiation there follows a latent stage of a few hours when a light gray discoloration of the epithelial membranes occurs. Blisters, ulcers and oedemas are never produced when the work is done carefully. Oedemas as part of the pathology are never influenced by ordinary doses. Flat ulcerations heal to an in-

visible little elevation which persists a long time, and which later on completely flattens out. Granulations become smaller and flatter, but one can always distinguish the place where the light acts from the place where it does not act. They become more and more epithelialized and after months can be noticed by the uneven surface. Infiltrations gradually become smaller until a pale green swelling remains which shrinks up to several wrinkles. Dysphasia usually subsides with the disappearance of the superficial sore. Sometimes a large tubercular lesion is cured in a few weeks, while a small one will heal only after months, which can be explained only by the general condition of the patient, the extent of the lung lesions and the different degrees of regenerative power. Ulcerations of the mouth, tongue and pharynx heal much faster than those of the larynx. The cure takes longer the deeper the ulcers lie.

In the series of cases which it was my privilege to watch, 33 per cent were cured, 35 per cent improved, 13 per cent improved temporarily, 8 per cent made a change for the worse, and treatment was interrupted, and 12 per cent discontinued treatment because of dissatisfaction.

My plea, then, is for a more systematic study of the larynx in all cases of tuberculosis followed by an examination at least once each month. Remember that rest is the first essential. Use the light therapy in any case which is afebrile, those patients who are in fairly good condition being subjected to the direct application of the ray while their less fortunate brothers attempt the easier form of treatment, namely, the indirect ray. If the light does not yield satisfactory results employ the actual cautery, scarring over the superficial ulcerated areas which are not on the chords, and which do not involve too much surface. With the cautery puncture the infiltrations when this seems advisable. If the epiglottis is badly involved associated with dysphagia amputate it, if there are pedunculated masses posteriorly bite them off and cauterize the bases.

Sir Sinclair Thompson said at Atlantic City in 1919 that among all fairly early cases of pulmonary tuberculosis admitted to the sanatoria in England, the expectation is that 60 per cent will be alive in from three to seven years, but in similar sanatoria patients admitted with the larynx involved only 30 per cent will be alive at the end of that period. We can appreciably lessen the latter figure if we will vigorously attack tubercular lesions in the larynx, particularly in those patients with inactive lung processes, by eliminating the larynx as a possible focus for reinfection of the lungs or new

THE ANNUAL MEETING IN NEW YORK CITY—1926

The State Society is fortunate in having as its officers men who are working conscientiously and tirelessly for the advance of the medical profession. Excellent proof of this is to be found in the elaborate programs which have been made by the Committee on Arrangements at the old Waldorf-Astoria for the comfort of the Association and the up-to-date presentation of advances which have been made in medical technique and instrumentation.

A word about our meeting place. On March 15, 1893, the late Mr. George Boldt opened the Waldorf. It was an event which required foresight and courage. To the casual observer the Waldorf-Astoria has always been a success. At

the start, it seemed anything but a success to Mr. Boldt. During the first summer, there was a Sunday when with 40 guests he had 970 servants on the payroll—plenty of reason to worry, but with the determination to give his guests every luxury and comfort, he made a reputation for the Waldorf-Astoria which is second to none.

Could the old walls talk, they would tell you of the unspeaking acquaintance William Waldorf Astor had with John Jacob—how the latter built a wall to close off the first Waldorf, then peace was made and the bigger and better combined hotel came. They might record how the Bradley-Martin ball, held here in 1897, was quoted for years to come, Li Hung Chang came, in 1902,

Prince Henry of Prussia made the hotel his official headquarters, and so the old Waldorf has endeared itself to those New Yorkers who by heritage expect the best

This is merely a tribute to the honest endeavor of a management which has had ideals and lives up to them, and so we feel in good company when in like spirit the Medical Society of the State gathers here

The scientific programs require no explanation. They have been carefully worked out and will offer every section the opportunity of thoroughly expressing itself. We would stress, however, the special demonstration on syphilis, which occurs Thursday morning, April 1. Of this we should take advantage, as rarely can one subject be so thoroughly assembled except at an annual convention.

Tuesday, March 30, is the night of the banquet. Merely to state that it is to occur at the Waldorf should assure a large attendance. The incomparable Oscar is just as interested now as in the past—we will be well cared for.

Owing to lack of accommodations at the Waldorf, the meetings of the Women's Medical Association of New York will be held at the McAlpin nearby. They are planning to welcome every woman physician from New York, New Jersey and Connecticut. They have stressed two very valuable suggestions for "out of towners"—first, a trip to the new Medical Center of Columbia University on Washington Heights. This is well worth while, although the buildings are still under construction, their substantial and impressive height carry a medical argument which words can poorly convey. Again, the Academy of Medicine is soon to open its doors on upper Fifth Avenue with a new building and added responsibilities. Those who are non-resident Fel-

lows should know where the new building is located.

The New York State Association of Public Health Laboratories will also convene on the evening of the thirtieth at the Waldorf.

The Commercial exhibits this year bid fair to excel anything we have had for years. The last issue of the Journal stressed the obligation the physician owed his various collaborators for better health.

Let us remember that everything commercial has not been commercialized—that the ethics of truthfulness and honesty of manufacture is just as much a part of manufacture as it is of medicine. The aim of the A M A and State Societies has been a progressive refinement in the claims of exhibitors. The survival of the fittest is an old rule, and hence we naturally expect to find old friends at the various booths.

Look things over carefully. Instruments cannot do the thinking or pass judgment, but if we do our own thinking, good tools will go a long way toward obtaining success.

New York will throw open its clinical doors, and by consulting the bulletin boards at the Academy of Medicine, subjects of every nature and kind will be found available for visiting members. Nineteen hundred and twenty-six should be a year of advance. Progress in medicine, however, is in proportion to the inspiration and endeavor of the individual.

Probably the greatest advantage in State meetings is the educational value on its membership and the broadcasting of mutual experience. To read a man's books and then to meet the author personally after the reading, adds a touch which is never gained in the abstract.

Let us have a speaking acquaintance with the Medical Profession and learn to know one another's names and faces.

THE MINERAL SPRINGS OF SARATOGA

The development of the mineral springs of Saratoga is included in the program for which the State of New York is issuing bonds. The State has already acquired several hundred acres of land around the springs, and has made available their facilities to some extent. The further plan is to use some of the one hundred million dollar bond issue that has been authorized and to develop the springs and the land around them into a park, and to provide the facilities for hydro-therapeutic treatments which shall be within the reach of the financial means of all classes of citizens. The plans are described in more detail in a communication on page 278.

The hydro-therapeutic values of the mineral waters of Saratoga fall into the three classes of internal, external, and environmental.

The original conception was that the principal value of the water was its internal effect after it had been swallowed like a drug. But extravagant claims for the water, its use self prescribed by laymen and quarrels over the ownership of the underground waters all combined to bring discredit on the waters, both in Saratoga and throughout the land.

When the art of physio-therapy, and of its subdivision, hydro-therapy, was developed and standardized, the value of the Saratoga water was rediscovered, and its external use was developed on an increasing scale.

Lastly, there came the realization of the therapeutic value of environment—extensive facilities, courteous attendants, happy convalescents, and beautiful surroundings. These attractions combined with the abundant use of the water

externally, and are conducive of effective therapeutics

Private ownership of the springs of Saratoga led to discord and failure, but they are a valuable asset in the State system of parks, and should not only be self-supporting, but also produce financial dividends to the State

Physicians are interested in the springs from a medical point of view. The medical societies of the city of Saratoga Springs and of the County of Saratoga are using their influence that the springs shall be developed along lines that are strictly scientific and ethical. They also in-

sist that abundant facilities for the use of the waters be placed at the disposal of people of moderate means, and that the springs shall not be exploited for the benefit of any one class of persons. The future reputation of the springs of Saratoga is in the hands of the local physicians, and to them the doctors of the rest of New York State will look for the assurance that the waters shall be developed according to the standards of science and medical ethics. Some one must see that these standards are maintained. Who can perform that duty better than the local medical societies?

SPECIAL PRIVILEGES

Hope springs eternal in the human breast and leads men to give at least one trial of anything that holds out a special promise of health and strength and vigor. There are numberless gold mines for those who have the self-assurance to claim special abilities in building the human body. When one man proclaims an alleged discovery, numerous imitators spring up, and in a short time they form an organization—a combination in the restraint of trade,—in order to shut out further competition from any others who aspire to work on their acres of diamonds. They claim as the basis of their unions the desire to purify and elevate their own ranks. They must claim this altruistic motive in order to give respectability and standing to their pretences.

The methods of the cults in seeking recognition are similar to one another and consist in going before the Legislature and asking for a special license. They offer to make future aspirants undergo a long period of training and to stand a stiff examination—the stiffer the test the better they like it—provided only that they themselves be permitted to continue in their operations. When a procedure becomes so well known that it can be capitalized, the last thing that those who are already in the field want is a further influx of competitors, and their object is to retain for themselves whatever advertising value may accrue to them from the names of their cults. A monopoly of their trade name is what they seek. Only one cult—one of the newer ones—is generous enough to seek a general law permitting anyone from practising any kind of manipulating of the human body.

The cultists know the advertising value of popular support, and they work their patrons to the limit in getting testimonials regarding the benefit of the treatments. A testimonial is about the cheapest thing they can obtain, but its advertising value is great. A testimonial, like a petition, is easily obtained even from judges and school teachers and ministers of the Gospel. A kind-hearted man is always ready to do a favor to another, especially if it involves no more effort than to write a brief note to a legislator. It is

no compliment to our legislators that cultists ask them to grant special privileges to the cultists. The healers place our legislators in a class with the unjust judge in the parable, who granted a woman's request "lest by her continued coming she weary me." Some legislators last year urged the physicians to "come to an agreement with the cultists and end this continued beseeching." The principal force back of the cultists is their persistence by which they expect to wear down the better judgment of the legislators. That is the object of their petitions and testimonials.

Legislators do not escape annoyance by granting the desires of a cult. When one group of healers obtain special privileges, all the other fifty-seven varieties of manipulators are straightway encouraged to redouble their efforts to obtain recognition. This year there are more bills than ever that are designed to grant special privileges to healers.

When a cult receives recognition, its votaries no longer confine themselves to the practices for which they are licensed, but they proceed to practice any form of treatment they choose. B. J. Palmer, the granddaddy of the biggest one of the groups, bewails the fact that the majority of those who assume the name of his cult use other practices to a greater extent than his own procedures. A group that is seeking recognition wishes to be licensed to make use of any therapeutic procedure it chooses—bone setting or spinal manipulation, or faith cure, or auto suggestion or anything else that is bait for the trap to catch the dollars.

Physicians have to meet the accusation that they too are seeking special privileges to practice the healing art, but such accusations harm only the accusers and show them up as men of small minds, unworthy to be entrusted with the responsibility of dealing with life and death in human beings. If special privileges be granted to healers, let it be those which come from four years of training in high-class institutions supplied with all the facilities which science and morality can endow.

THE PHYSICIAN'S BUSINESS PARTNER

The doctor is dependent on a number of other persons who are highly skilled in various trades and professions. He could not practice medicine without the aid of instrument makers, from the highly skilled mathematician who designs lenses for microscopes, to makers of scalpels and braces. He is dependent on the chemists, botanists, and zoologists who prepare his medicines and serums, and standardizes their doses with exactness. He must have the services of workers in iron and brass and wood to prepare his office furniture and equipment. The printer and publisher prepare the books and periodicals which endow his mental equipment.

All these craftsmen and technicians are friends of the doctor. They fabricate their products to suit his needs and desires, and they invent new instruments to enable him to operate with precision, certainty, and ease. They design new office equipment for his comfort and convenience. They delve into the secrets of nature and produce new products for his use.

The methods of the craftsmen are those of the business world. They make the great bulk of their products with the expectation that doctors will appreciate their workmanship, and will come to them and buy what they need. The stock which they carry at their own expense is a great

incentive that stimulates the doctor to have the most modern equipment that he can afford,—and he cannot afford to have anything less than the best. Caesar recognized the civilizing value of the services of the merchants when he said that the Belgians were the least civilized of all Gauls because the merchants resorted to them the least often. The doctor, too, feels the urge to better practice of medicine when he receives the visits of the vendors of instruments and books and office equipment and drugs.

A meeting of a great medical society, such as that of New York State, is not complete without its exhibit of commercial products which the doctor uses in his practice. The exhibitors at the annual meeting of the Medical Society of the State of New York are those whose products and methods are approved by the American Medical Association, and whose ethics are as upright as those of the medical profession. They are on the same floor with the doctors' assembly rooms. The doctors may see the products and test them, and may have their virtues explained by expert demonstrators.

The exhibits are part of the program that was designed by the Scientific Committee. They are coordinate with the scientific sessions, and deserve the same attention from the doctors.

LOOKING BACKWARD—THIS JOURNAL A QUARTER CENTURY AGO

The campaign for the eradication of diphtheria is founded on certain knowledge of definite tests which are in marked contrast with the uncertainties of the days a quarter a century ago when the data was being collected slowly and laboriously and the interpretation of the findings had not passed beyond the experimental stage.

This JOURNAL for March, 1901, contains a report of some cases of diphtheria which were classed as unusual. Case 1, a boy four years old, had a sore throat and rhinitis, and the doctor, who was thoroughly informed regarding the value of diagnostic tests, took a culture twenty-four hours later and was surprised to receive a report of the presence of diphtheria bacilli. He immediately gave 2,000 units of antitoxin "although no exudate was visible." In twelve hours the child discharged two large pieces of membrane from its nose. Thirty-six hours later a membrane appeared on the posterior wall of the pharynx and 1,000 units of antitoxin were given and Loeffler's solution was applied to the exudate. The boy was nearly well within two days, and

the diphtheria bacilli had disappeared from the throat ten days later.

The second case was that of a nurse, aged 24, who had a sore throat and a cough. She was cultured and on the receipt of a positive report, 2,000 units of antitoxin were given and Loeffler's solution painted on the throat and repeated until by the end of eighty hours she had received 6,500 units. She continued to cough and to have fever, and pneumococci were found in the sputum. The bronchitis ran its course, the diphtheria bacilli disappeared from the throat in nine days and the case left the hospital in twenty-eight days. A complication was a rash during the second week of the disease. The author comments:

"The cases illustrate the value of large doses of antitoxin given early, together with the local application of Loeffler's solution. Had it not been for the examination of the sputum (in the second case) we might have been justified in considering the bronchitis and the pneumonia as diphtheritic in origin, and might have continued giving even larger doses of antitoxin."

externally, and are conducive of effective therapeutics

Private ownership of the springs of Saratoga led to discord and failure, but they are a valuable asset in the State system of parks, and should not only be self-supporting, but also produce financial dividends to the State

Physicians are interested in the springs from a medical point of view. The medical societies of the city of Saratoga Springs and of the County of Saratoga are using their influence that the springs shall be developed along lines that are strictly scientific and ethical. They also in-

sist that abundant facilities for the use of the waters be placed at the disposal of people of moderate means, and that the springs shall not be exploited for the benefit of any one class of persons. The future reputation of the springs of Saratoga is in the hands of the local physicians, and to them the doctors of the rest of New York State will look for the assurance that the waters shall be developed according to the standards of science and medical ethics. Someone must see that these standards are maintained. Who can perform that duty better than the local medical societies?

SPECIAL PRIVILEGES

Hope springs eternal in the human breast and leads men to give at least one trial of anything that holds out a special promise of health and strength and vigor. There are numberless gold mines for those who have the self-assurance to claim special abilities in building the human body. When one man proclaims an alleged discovery, numerous imitators spring up, and in a short time they form an organization—a combination in the restraint of trade,—in order to shut out further competition from any others who aspire to work on their acres of diamonds. They claim as the basis of their unions the desire to purify and elevate their own ranks. They must claim this altruistic motive in order to give respectability and standing to their pretences.

The methods of the cults in seeking recognition are similar to one another and consist in going before the Legislature and asking for a special license. They offer to make future aspirants undergo a long period of training and to stand a stiff examination—the stiffer the test the better they like it—provided only that they themselves be permitted to continue in their operations. When a procedure becomes so well known that it can be capitalized, the last thing that those who are already in the field want is a further influx of competitors, and their object is to retain for themselves whatever advertising value may accrue to them from the names of their cults. A monopoly of their trade name is what they seek. Only one cult—one of the newer ones—is generous enough to seek a general law permitting anyone from practising any kind of manipulating of the human body.

The cultists know the advertising value of popular support, and they work their patrons to the limit in getting testimonials regarding the benefit of the treatments. A testimonial is about the cheapest thing they can obtain, but its advertising value is great. A testimonial, like a petition, is easily obtained even from judges and school teachers and ministers of the Gospel. A kind-hearted man is always ready to do a favor to another, especially if it involves no more effort than to write a brief note to a legislator. It is

no compliment to our legislators that cultists ask them to grant special privileges to the cultists. The healers place our legislators in a class with the unjust judge in the parable, who granted a woman's request "lest by her continued coming she weary me." Some legislators last year urged the physicians to "come to an agreement with the cultists and end this continued beseeching." The principal force back of the cultists is their persistence by which they expect to wear down the better judgment of the legislators. That is the object of their petitions and testimonials.

Legislators do not escape annoyance by granting the desires of a cult. When one group of healers obtain special privileges, all the other fifty-seven varieties of manipulators are straightway encouraged to redouble their efforts to obtain recognition. This year there are more bills than ever that are designed to grant special privileges to healers.

When a cult receives recognition, its votaries no longer confine themselves to the practices for which they are licensed, but they proceed to practice any form of treatment they choose. B. J. Palmer, the granddaddy of the biggest one of the groups, bewails the fact that the majority of those who assume the name of his cult use other practices to a greater extent than his own procedures. A group that is seeking recognition wishes to be licensed to make use of any therapeutic procedure it chooses—bone setting or spinal manipulation, or faith cure, or auto suggestion or anything else that is bait for the trap to catch the dollars.

Physicians have to meet the accusation that they too are seeking special privileges to practice the healing art, but such accusations harm only the accusers and show them up as men of small minds, unworthy to be entrusted with the responsibility of dealing with life and death in human beings. If special privileges be granted to healers, let it be those which come from four years of training in high-class institutions supplied with all the facilities which science and morality can endow.

with attacks of giant urticaria. These attacks were followed by general epileptic convulsions which were clonic throughout, thus being primarily caused by cortical irritation. Protein sensitization tests proved the child susceptible to milk, which was discontinued with the result that there were no further attacks of urticaria or convulsions. In the second case, a middle-aged man, who had suffered for ten years from attacks of circumscribed edema affecting the soft palate, lips, cheeks, and occasionally the arms and trunk, had four attacks of hemiplegia associated with the edema. Two of these attacks affected the left side and two the right. In both attacks involving the left side of the brain there was complete motor aphasia, in no instance was there any sign of disease thirty-six hours after the attack. In a third patient, a man aged 28 years, who had suffered from severe attacks of angioneurotic edema for five years, there were numerous attacks of acute transient edema of the optic nerve and retina resulting in total loss of vision, from which the patient recovered in from a few days to several weeks. There were also other transient phenomena affecting the central nervous system—complete aphonia, deafness in both ears, difficulty in swallowing, and hemiplegia—which were seemingly synchronous with those seen with the ophthalmoscope. The patient showed sensitization reactions to milk and veal. Kennedy suggests that acute perivascular edema may play a part in some of the malignant types of insular sclerosis. If external poisons can cause cerebral episodes such as these, they may also cause the transient episodes of Charcot's disease of which the morbid process has been so baffling.

Dementia Precox in Identical Twins—

While a growing interest has been shown in the biological significance of twins, very little attention has been paid to their diseases, especially to their mental diseases. Siemens, in 1924, noted seventeen recorded instances of dementia precox among them. Of the seventeen pairs, six were without doubt identical, five were less certainly so, and six were probably fraternal. Franz, in 1919, reported the case of a pair of twins suffering from dementia precox, he dealt with the subject from the standpoint of nervous disease strictly and did not enter into a discussion of the biological problems involved. G. H. Parker (*Journal of Nervous and Mental Diseases*, February, 1926, LIII, 2) describes another instance of this condition in twins, which is similar in many respects to that reported by Franz. Both of these twins showed symptoms of dementia precox, following an attack of diphtheria, at the age of sixteen years, though in one of the twins the symptoms did not manifest themselves until several months after the attack. The resemblance of the symptoms in twins was very striking. The simultaneous occurrence in identical twins of children's diseases, such as chicken-pox and the like, is more probably an environ-

mental affair than a germinal one, but with the occurrence of dementia precox in such twins the evidence is strongly in favor of a germinal source, since this disease seems to have been attributed to infection. It appears to arise from a germinal taint, a maladjustment of the egg cell or the sperm cell or both. In Parker's case the father of the twins had suffered a sunstroke, and thereafter was hypochondriacal and depressed and occasionally talked of suicide. That the mental disease should also occur in pairs of fraternal twins, as noted by Siemens, is no argument against this view, for, if it is germinal in nature, it may well be expected in any of the members of a given family. What would be of great interest in this connection would be the discovery of a case of dementia precox in only one of identical twins. The conclusion that dementia precox is germinal in origin is quite in line with what has been maintained within recent years about this disease, and with the statement of so conservative a writer as Myerson who declares that "dementia precox breeds true." From the practical standpoint the occurrence of this disease in one member of a pair of twins should lead the examining physician to an immediate examination of the other member.

Hepatic Function in Health and Disease—

The new facts concerning liver function that have been recently brought out are reviewed by Charles H. Mayo (*Surgery, Gynecology and Obstetrics*, January, 1926, VIII, 1), who describes the method developed by Mann for the total removal of the liver. This accomplishment has removed many of the difficulties that have stood in the way of the investigation of liver function. Mann and his co-workers, Magath and Bollman, found that when the liver was totally removed, the blood sugar level was greatly lowered, until, at a definite point, an animal which had shown little apparent disturbance from the loss of the liver, suddenly developed muscular weakness and in a short time became moribund. However, the injection of glucose, 0.25 to 0.5 gram to each kilogram of body weight, restored it immediately to normal. If the blood sugar is maintained at approximately normal level by the administration of glucose, the animal may be sustained in a comparatively active condition for many hours. A portion of bilirubin is produced in the liver but it is also made outside the liver from hemoglobin in the reticulo-endothelial areas of the body. The amino acids are taken up from the intestines by the blood, and those which cannot be employed to restore tissue are changed by the liver into glucose and urea. When the liver is totally removed, urea is not formed, and uric acid is not destroyed, proving that the liver is necessary for these important phases of nitrogen metabolism. Ligation of the common duct distends the gall-bladder and increases its function of filtration of fluids. If the gall-bladder is removed or the cystic duct ligated, bile pigment appears in the blood in

MEDICAL PROGRESS

The Influenza Pandemics of 1890 and 1918—Pirquet has made an exhaustive study of the age-mortality curves of these two pandemics, based upon the English mortality statistics and while inclining to the belief that the disease in each case was the cause, admits that those who hold the contrary opinion are not without strong arguments to support their view. He first eliminates the annual seasonal influenza which has prevailed since the 1890 episode, because from first to last it shows the age-mortality curve of acute bronchitis and might therefore be regarded as belonging essentially under this head. The pandemic of 1890-1 showed a minimum mortality during the period ending at 10 years, then a slow rise to the age of 25, after which came a rapid rise up to the 70's and after. This is assumed to be the natural mortality, in a population of non-immunes, from pandemic influenza. If now we compare with this curve the curve of the pandemic of 1918-21 we shall find such a startling difference that most of us would declare against the identity of the two. There was agreement as to the minimum mortality of the first decade of life, but after this there was sudden increase with maximum at 30 years. The death rate of the third decade was shocking. After 30 there was a steady decline up to 70. Admitting that this is a valid argument for separate disease processes, Pirquet calls attention to the factor of immunization of the public by the earlier pandemic. The fearful mortality of the 20-30 age period could be explained by the fact that the victims were non-immunes, while the middle aged and elderly who got off easily were immunes. This does not explain everything—for example, why did the young men escape in 1890 when they were not immunes either? The author is not entirely clear on this point but states in one place that in 1890 influenzal broncho pneumonia and lobar pneumonia were probably not included in the influenza figures, which conclusion would seem to vitiate his reasoning to some extent.—*Wiener medizinische Wochenschrift*, January 2, 1926

Wheal Formation in Infants and Children—As it has been observed that the wheal formation of urticaria is modified in a measurable degree in cases of cardiac edema, J. D. Pilcher thought it might be of interest to study it in other conditions, in the hope of obtaining information as to the condition of the skin vessels, especially in relation to their permeability, in such abnormal conditions. (*American Journal of Diseases of Children*, January, 1926, xxi, 1) As is well known wheals are produced by a large number of unrelated substances, notably his-

amine, members of the morphine group, and proteins. In this study codeine, whose action is identical with that of morphine, was chosen as the wheal-causing agent. Shortly after the intradermal injection of 0.15 cc. of a 1:1,000 codeine solution, a flush appears, which is soon followed by a wheal at the site of injection, the flush reaches its maximum within five minutes, the wheal a little later, in from ten to fifteen minutes the flush begins to fade, the wheal loses its sharp outline and gradually both disappear, the wheal outlasting the flush. Pilcher concludes that wheal formation in the skin is a manifestation of increased permeability and dilatation of the minute vessels. An efficient circulation is necessary for wheal formation. This phenomenon was lessened in all cases of edema studied, regardless of the cause, whether nephritis, cardiac decompensation, leucemia, malnutrition from starch-feeding, injury, and also in the local skin edema of serum-urticarial wheals and of those following the injection of saline infusions. This result is due to the edema itself and not to decreased vessel permeability. Wheal formation is also lessened in certain ill-defined skin infiltrations, namely, in cretinism and myxedema and in sclerema and scleredema. In nephritis without edema, the wheal formation, and hence the vessel permeability, is normal, indicating that the cause of the edema in nephritis is not increased vascular permeability. In valvular and congenital heart disease without edema, even with considerable decompensation, the wheal formation is normal, indicating an efficient circulation in the skin. In myocardial degeneration and in certain cases of severe prostration, wheal formation is diminished because of a lessened circulation in the skin. A normal wheal reaction indicates an efficient circulation at the site of the wheal. The presence of a strongly positive tuberculin reaction does not modify wheal formation. Low serum calcium and phosphorus, down to half the normal quantity, in infants with rickets or spasmophilia, have no influence on the permeability of the minute vessels of the skin, as measured by the codeine wheal reaction.

Cerebral Symptoms Induced by Angioneurotic Edema—Foster Kennedy (*Archives of Neurology and Psychiatry*, January, 1926, xv, 1), presents evidence showing that the statement, often reiterated in the literature, that brain vessels are incapable of variation in size is incorrect. He reports three cases in which cerebral symptoms were apparently induced by angioneurotic edema affecting the brain. The first case occurred in a child of two years, who suffered

ject in the recumbent position. There is, of course, a brief loss of consciousness. Collapse is a complicated condition and for some time consciousness is retained although there is a late loss of it. Swoon is by no means peculiar to the weak and nervous for the author has seen it in robust butchers used to the sight of blood. We can describe it only as an increased vasolability. In collapse the entire organism suffers a partial suspension of function although the blood-vessels exhibit the greatest departures. There are various forms of collapse as hemorrhagic, cardiac, vasomotor (seen in acute infectious diseases), and toxic (in pancreatic necrosis). In regard to the vegetative nervous system we have learned much about it in the past 15 years, not only its peripheral portion but its special nerve centers which lie mostly in the mesencephalon, hypothalamus, walls of the third ventricle, crura cerebri, etc. These centers are believed to stand in a definite relation with water retention, nutrition and body weight. The author believes that the seat of swoon is in the cerebral peduncles, where, as stated above, the vegetative nerve center is believed to be located. Swoon, he believes, is always basal, never cortical in origin. The author attempts to make a valid distinction between shock and collapse. The latter is a far more common and manifold and complicated condition than shock and when we say shock we usually mean collapse. We should not speak of "shock" from hemorrhage or "shock" from septic or toxic influences, or anaphylactic "shock" but in all such cases should be substituted the term collapse. The two conditions have many similarities and many symptoms in common such as the weak, rapid, and thready pulse, the subnormal temperature and the cold and clammy skin, with the slowing of the cerebral functions and retention of consciousness. Moreover shock may pass into collapse. But there are differences, for shock comes on suddenly or we would not call it shock. It is therefore chiefly traumatic in origin and for the same reason it is reflex in mechanism. The initial and key alteration is sudden lowering of blood pressure. After a careful analysis of shock theories the author decides that shock is preëminently neurogenic, and that the vegetative nerve system is involved in the reflex. It could be called traumatic neurogenic collapse. Through the part played by the vasomotor nerve system the vessels suddenly dilate and lower the blood pressure. The author goes back to the old teaching of H. Fischer in 1870 that there are two forms of shock, the ordinary or torpid form and the erythemic which is characterized by delirium, jactitation, etc. One form may succeed the other, and the erythemic form is closely allied to psychic shock which may or may not follow physical injury. Moreover there is a local form of shock limited to the abdominal cavity such as develops from abdominal contusion.

Statistics of Diphtheria Treatment in Copenhagen—Heckscher, associated with Professor Bie, reports nearly 5,000 (4,819) cases of diphtheria treated with serum at the Blegdam Hospital, Copenhagen, during the period 1921-1925. The total mortality is given as 12 per cent. Somewhat over 10 per cent of this material, or around 500 cases, represented the severe form of the disease and required very large doses of serum—up to 200,000 units per case. The special mortality of the severe cases is not given, although the total number of deaths (96) most probably occurred here. The author, however, points out that in 28 cases the cause of death had nothing to do with diphtheria or its treatment for the patients died of concurrent diseases or accidental complications, including ordinary pneumonia, acute phthisis, congenital syphilis, etc. Deducting this number we have 68 deaths from the disease itself, inclusive of one from serum sickness. If we assume that the 68 deaths occurred among the 500 patients with severe diphtheria the special mortality would be slightly under 14 per cent which certainly speaks well for serum treatment. The chief mechanism of death was circulatory collapse and no less than 62 cases terminated in this manner, 11 within a very short period after the onset of the disease. The practice of giving such large injections has naturally its disadvantages, for the majority developed some serum sickness, while in addition to one death set down to this cause it may have been a factor in two others. The interested reader is referred to a forthcoming number of the *Acta Medica Scandinavica* in which the material is to be reported in detail—*Deutsche medizinische Wochenschrift*, January 8, 1926.

Studies of Certain Hitherto Undescribed Antirachitic Substances—In former communications Andor de Bosanyi (*Bulletin of the Johns Hopkins Hospital*, January, 1926, xxxviii, 1) showed that watery extracts of defatted bone-marrow caused healing when they were administered to rickety animals. Since the bone-marrow from which these substances were made was defatted, and the extracts themselves were subjected to dialysis, the organic matter must have consisted in a large part of protein. Among these proteins hemoglobin, histons, nucleoproteins, fibrogen, and globulins are the most notable; there are also some xanthin bases, cholesterin, inositol, lactic and uric acids, and certain pressor substances. Experiments were carried out to determine to which of these substances the specific antirachitic effects were due. Rats were made rachitic by standard rickets-producing diets and then treated with these substances, given separately. It was found that healing might be induced by a histon—the globin of hemoglobin, a diamido acid, cystin, an aromatic compound, adrenalin, and an alkaloid, pilocarpine.

amounts sufficient to give a positive van den Bergh test in from three to six hours and jaundice in twenty-four hours. Excess of fatty bodies in the blood and toxins of infection may as suddenly start and complete the formation of a stone, or the addition of another layer to a stone, as a hen can cover an egg with carbonate of lime, that is, in one day. The conception of disease of the gall-bladder from overwork is being recognized as the basis of the development of gallstones. Excess of sugar (and the amount consumed by one individual has increased a pound a year for 100 years, being now about 112 pounds) causes hyperfunction of the liver and of the cystic, common and hepatic ducts. Stimulation of the sympathetic nervous system may be the result of changes in hepatic function, dependent, in turn, on injudicious eating and the strain of modern ways of living. Bile in the blood from obstruction of the common duct greatly delays coagulation time and increases the risk of operation during jaundice. At the Mayo Clinic such patients receive 5 c c of a 10 per cent solution of calcium chloride once daily for three days preceding operation. In persons chronically sick, who have taken little food for weeks, sugars are given by mouth and glucose by bowel, if required, before or after serious operation. By such conservative methods the old death rate of 10 to 15 per cent attending operations in the presence of jaundice has been lowered to 3.5 per cent. In certain cases in which the liver is not functioning adequately, the administration of bile frees the gall-bladder under tension during fasting. The flow of bile is increased by ox-gall and nitrogenous food, rich carbohydrate food checks it. In chronic deficiency of the liver, with cirrhosis and splenic enlargement, removal of the spleen reduces by 20 per cent the work of the liver, thus relieving and conserving the organ.

Ascites Complicating Cirrhosis of the Liver Treated by Novasurol—J. Gordon Anderson (*Boston Medical and Surgical Journal*, December 31, 1925, cxciii, 27) reports a case of alcoholic cirrhosis occurring in a man, aged 61, in which paracentesis performed on two occasions afforded only temporary relief. Novasurol treatment was then instituted. A preliminary subcutaneous injection of 0.6 c c showed that there was no idiosyncrasy to the drug. Nine injections, at intervals of four to six days were given during a month—a total of 12 c c of the drug being administered. Marked diuresis followed the injections. During the treatment the patient was kept on a low fluid intake with 90 grains of ammonium chloride daily. The abdominal circumference was reduced 15.6 cm., and the patient's weight sixteen pounds. The dyspnea disappeared, as did the physical signs of fluid. Of the various medicinal means which have been used to relieve ascites in cases of cirrhosis of the liver, intravenous injections of novasurol are not

only the most effective, but do not impair to patient's general strength. It is also less irritating to the kidney than other diuretics. If novasurol alone fails to produce a satisfactory diuresis, the additional use of ammonium chloride often brings about the desired result. This treatment is advocated for patients whose general condition is poor, who suffer from advanced cardiac disease, and in whom the functional activity of the liver cells is greatly reduced. It is not intended to replace or postpone operation in cases in which the indications for this more radical form of treatment are favorable.

Non-Surgical Aids in the Treatment of Surgical Patients—Albert J. Ochsner (*American Journal of Electrotherapeutics*, December, 1925, xliii, 12) comments on the ease with which a person working in one field of medicine gradually acquires the conviction that patients who are really sick can be cured only if subjected to his especial type of treatment. He states that he has seen very remarkable results from the systematic application of sunlight or its artificial equivalent in the treatment of tuberculous conditions, with or without the use of surgery, as indicated in the case in question. In cases of septic infection of the extremities the use of large hot moist dressings with a saturated solution of boric acid and alcohol under an ordinary cone reflector containing an electric light will change a very serious acute condition, which frequently requires one or more extensive operations, into a relatively safe and simple condition requiring at most a slight incision. In conditions due to sprains and contusions Ochsner constantly makes use of the Preisnitz pack. He finds that a very large number of surgical patients can be benefited to a remarkable extent by the use of massage and gymnastics scientifically applied. Too little attention is given by surgeons to this form of physical therapy. There seems to be no doubt concerning the value of mineral baths. The two most valuable physical aids to the surgeon are x-rays and radium. For the past six years, the author has placed all cases of carcinoma of the uterus coming under his care in the incipient stage of the disease on treatment with radium and x-rays. In the early cases he removes the uterus with the cautery. Of those treated with radium and the x-rays, many are alive and well today, who would undoubtedly have died long ago, had dependence been placed on surgery alone for their treatment.

Swoon, Shock and Collapse in Relation to the Vegetative Nervous System—Coenen discusses this subject in the *Muenchener medizinische Wochenschrift* of January 4 and 8, 1926. Little is said of swoon, save that the author is no believer in the existence of fatal swoon, but holds that cases of this kind will be found on autopsy to be due to some severe organic lesion. Swoon is corrected simply by placing the sub-

ject in the recumbent position. There is, of course, a brief loss of consciousness. Collapse is a complicated condition and for some time consciousness is retained although there is a late loss of it. Swoon is by no means peculiar to the weak and nervous for the author has seen it in robust butchers used to the sight of blood. We can describe it only as an increased vasolability. In collapse the entire organism suffers a partial suspension of function although the blood-vessels exhibit the greatest departures. There are various forms of collapse as hemorrhagic, cardiac, vasomotor (seen in acute infectious diseases), and toxic (in pancreatic necrosis). Charities Aid Association, the writer, as counsel for the State Medical Society, and others

It was interesting to note that the principal attack came from the organized chiropractors Mr Newton B VanDerzee, counsel for the State Chiropractic Association, and "Dr" Linden Lee, past president of the State Chiropractic Association, spoke at length against the bill. Their opposition was based upon the ground that it would make the practice of chiropractic more difficult. This argument is perhaps the best guarantee of the value of the bill and should strongly tend to commend it, not only to the licensed physicians of this State, but all those who are working for the public health. The fact that those who for their own gain practice upon public credulity under the guise of chiropractic or other quackery oppose this bill is an argument in its favor which speaks for itself.

Perhaps the essential and most important provision of the bill is that providing for the creation of a grievance committee. This committee is to be composed of ten licensed physicians appointed by the Board of Regents, four of whom are appointed out of twelve nominees to be submitted by the Medical Society of the State of New York, two out of six nominees to be submitted by the New York State Homeopathic Society, one out of three nominees to be submitted by the New York State Osteopathic Society, and the bill provides that "the regents upon their own nomination shall appoint three members of conspicuous professional standing." The committee is given "jurisdiction to hear all charges against duly licensed physicians" of this State for violations of the provisions of Section 174a of the bill, except subdivision 1 thereof, which provides for the automatic revocation of the license of a physician who has been convicted of a felony as defined by Section 161 of the article. The grievance committee, therefore, has jurisdiction to hear and determine all charges against a physician who has been guilty of "fraud or deceit in the practice of medicine or his admission to the practice of medicine", who has been convicted in a court of competent jurisdiction either within or without this State, of a crime or misdemeanor", who "is an habitual drunkard or addicted to the use of morphine cocaine or other drugs having similar effect, or has become insane who has been 'guilty of untrue fraudulent, misleading or deceptive advertising or advertising that he can cure or treat disease by a secret method, procedure, treatment or medicine, or that he can treat operate and prescribe for any human condition by a method, means or procedure which he refuses to divulge upon demand to the committee on grievances," and one who undertakes or engages 'in any manner or by any ways or means whatsoever to procure or to perform any criminal abortion or to violate Section eleven hundred and forty-two

of the penal law," making contraceptive advice unlawful.

Discussion has been had concerning the provision empowering the grievance committee to revoke a license for the conviction of a 'misdemeanor' (Sec 174a, sub 2b). For instance, in the *New York Medical Week* of March 6, it is said

'Spitting in the subway, though in undeniably poor taste, should hardly be made even a remotely conceivable pretext for ousting a man from his profession. While it is unlikely that minor misdemeanors would ever be used to deprive a physician of his license, the law should not leave the perpetration of an injustice to anyone's discretion.'

The answer to this suggestion is plain. There are certain misdemeanors which are of a sufficiently serious character, or, as the law says, *mala in se* which might in the judgment of the grievance committee be an adequate basis for the revocation of a license or other discipline of a physician. But it should be recalled that the grievance committee is to be composed of the peers of the accused, it is to consist of duly licensed physicians of high professional standing and unquestioned character. To suggest that this committee so composed would unwarrantably revoke a license or discipline a physician for spitting in the subway or other trivial offense could only be made if the doctors composing this committee were unworthy of trust and confidence. It must be assumed that the physicians who sit upon this committee will be men of ordinary common sense, integrity and judgment, and will not arbitrarily or foolishly exercise the powers committed to them to the undue detriment of any physician. This assumption rests upon the confidence which the physicians of this State must have in their professional brethren who, under the terms of the bill, will compose the grievance committee.

The bill provides clear and effective machinery for the operation of this grievance committee. It provides that the accused may be heard either in person or by counsel, that he can submit evidence and subpoena witnesses in his own behalf. It also provides that the committee "shall not be bound by the laws of evidence in the conduct of the proceedings but the determination shall be founded upon sufficient legal evidence to sustain the same." This is an extremely salutary provision. It requires the committee to have sufficient legal evidence upon which to base its decision, but the presentation of proof other than legal evidence is permitted. In this way the accused doctor could present to the committee all those matters which would throw light upon his innocence and tend to explain the charges against him, which would not be admissible in a court of law. But when it comes to the making of an adverse decision the committee is bound

LEGAL

By LLOYD PAUL STRYKER, Esq
Counsel, Medical Society of the State of New York

THE PROPOSED MEDICAL PRACTICE ACT OF 1926

No measure affecting the practice of medicine has ever been more thoroughly considered or more fully represents the opinion of the profession than the proposed Medical Practice Act now pending before the legislature.

At the last annual meeting of the House of Delegates, a resolution was adopted providing for the appointment of a Committee of Seven to draft, present and, if possible, to secure the passage of a new law governing the practice of medicine in the State of New York. In conformity with this resolution, your distinguished President, Dr Nathan B VanEtten, appointed the following Committee: Dr John E Jennings, Dr George M Fisher, Dr Thomas C Chalmers, Dr George A Leitner, Dr James E Sadler, Dr George B Stanwix and Dr Frederick H Flaherty. These gentlemen are not only eminent in their profession and thoroughly conversant with its problems, but by reason of their public-spirited service in their various communities are intimately in touch with the particular point of view of the localities from which they come.

The committee met once every two weeks in New York City throughout the summer of last year and made the most painstaking and comprehensive study of the present law and of the need for its amendment, change, improvement and strengthening. They met not only with a frank and generous spirit of conciliation, but with the firm determination, irrespective of personal differences, to hear and consider all the questions involved, with an open mind and a readiness, if need be, to sink personal differences in an effort to evolve the best practicable measure that could be drawn and passed. After they had concluded their deliberations they then conferred with the Attorney-General's office and with the representatives of the State Departments of Health and Education, as a result of which some modifications were made in their first draft of the bill.

A conference was held on February 4, 1926 in New York City, at which the members of this committee and the legislative committee, members of the Board of Regents and a representative of the State Department of Education were present. Once more the measure was fully and thoroughly discussed. Finally, in Albany, on February 10, 1926, a meeting was held of the chairmen of the legislative committees of the various county societies. The meeting was held in the midst of the worst blizzard of the

winter, nevertheless, some forty counties were represented. Again, the measure was thoroughly discussed and considered. At this meeting a vote was taken, and all of the counties present, with the exception of one, voted to approve and support the bill. It has been a source of wonder and admiration on the part of the writer to see how much of their valuable time and effort the doctors entrusted with the duty of drafting this proposed law have unselfishly given to this work designed for the benefit of the entire profession—not only for the benefit of the profession, but for the public health and general welfare of the people of this State.

The draftsmen of the proposed act lay no claims to omniscience, nor do they assert that their work is perfect. No human effort is perfect. No man or group of men are infallible. Perhaps the most perfect document ever written is the United States Constitution, and even that has been amended many times and did not, when it was originally drawn, by any means satisfy all the wishes and desires of the disinterested statesmen who sought to weld the warring colonies into "a more perfect union." What is claimed, however, is that the bill represents the conscientious, painstaking and thorough deliberation of disinterested and public-spirited medical representatives of the various sections of this State, that it is the best practicable measure which could be agreed upon, and that it is a vast improvement over the present law and should be of benefit not only to the medical profession, but to the laity as well.

The bill was introduced in the Assembly on February 16, 1926, by Assemblyman Loomis, and in the Senate on February 18, 1926, by Senator Webb. On March 3, 1926, a public hearing was had before a joint committee of the Senate and the Assembly in the Capitol at Albany. This meeting was attended not only by a large delegation of physicians, but also by representatives of various charitable organizations and others who are vitally interested in problems of public health. Among those who spoke in behalf of the bill were Dr Wendell Phillips, the President-elect of the American Medical Association, Dr Nathan B VanEtten, President of the State Medical Society, Dr Henry L K Shaw, chairman of your legislative committee, Dr Louis I Harris, Commissioner of Health of the City of New York, Homer Folks, secretary of State Committee on Tuberculosis and Public Health of the State

of registration fees Every practitioner embarking upon the practice must pay a fee of \$2 00 and must thereafter pay annually the same sum These registration fees assist to provide the sinews for enforcing the act. The act provides that each year the physician must register, but this provision is made so reasonable that it is felt no burden will be imposed The secretary of the board of medical examiners must mail, on or before October 1 of each year, to each registered physician a blank form of application for registration The physician then has three months in which to make out this registration and send his check for \$2 00 The burden thus entailed from the financial point of view, of course, is negligible, and from the standpoint of annoyance or inconvenience it is reckoned that it will not consume more than three minutes of the doctor's time once each year As compared with the provisions of the law requiring registration for voting, annual registration of automobiles and the innumerable other provisions which in our complicated system are now required of all citizens, this requirement for annual registration is negligible. Its value should be apparent to everyone Its purpose is not only to provide the sinews with which to enforce the public health law, but to provide and keep up to date an authorized list of licensed physicians The bill expressly provides that upon the first of March each year a list of the registered physicians shall be mailed to every registered physician of the State, together with a request that he furnish to the secretary of the board of medical examiners or to the secretary of any State medical society "the name and address of any person known to be practicing medicine whose name does not appear in this registry" In this way every doctor in the State will be enabled to assist the authorities in weeding out the unlicensed charlatans who are preying upon the public The benefits thus derived from annual registration immeasurably outweigh the slight attendant inconvenience which it causes This has now been recognized throughout the State by nearly all physicians

No law could be drawn that would entirely satisfy everyone This law is more universally satisfactory, it is believed, than any similar measure that has ever been proposed Those who still entertain any feeling against annual registration we feel sure will do as Alexander Hamilton, one of the great patriots of the Revolution, so gloriously did when he supported the United States Constitution, although it contained innumerable provisions of which he did not approve His aim was the establishment of the American union and he was willing to submerge personal differences for the attainment of that great end The aim of every licensed physician of this State is the improvement of his profession and the safeguarding of the public health The

proposed Medical Practice Act is designed and it is believed will accomplish great results in furtherance of that aim

The bill expressly provides that the failure to register or pay the annual fee shall result in civil penalties only, and that the license of the doctor who has neglected to register "shall not be affected thereby," and further, that "such penalties may for good cause and in the discretion of the regents be remitted or compromised"

There is not space here for the discussion of many of the other important provisions of the bill Brief reference, however, should be made to subdivision 6 of Section 174 providing that "in any action for damages for personal injuries or death against a physician not licensed hereunder for any act or acts constituting the practice of medicine as herein defined, when such act or acts were a competent producing proximate or contributing cause of such injuries or death, the fact that such person practiced medicine as herein defined without being duly licensed shall be deemed prima facie evidence of negligence" This provision will be of great benefit to the unfortunate dupes of the unlicensed charlatan into whose hands they may come It will surmount the difficulty which was recently discovered in the case of *Brown v Shyne*, decided by the Court of Appeals on February 24 of this year In that case, the trial judge charged the jury that the fact that the chiropractor who by his treatment had caused paralysis was not a licensed physician "is some evidence more or less cogent of negligence which you may consider for what it is worth, along with all the other evidence in the case" The verdict of the jury awarding damages inflicted by that chiropractor was reversed because of this charge. The provision of the bill just quoted provides a statutory rule of evidence which in the future would enable a judge to make the charge which was the basis of the reversal in the Brown case This will be an additional curb upon the chiropractors and other quacks

The proposed act has attracted wide and favorable attention, not only on the part of physicians, but from the intelligent laity as well No more effective conclusion for this article could be found than the editorial of the New York Times of March 5, 1926, which is headed "Registration Entirely Reasonable," and is as follows

"Discouraging, indeed, is it, but by no means surprising, that the representatives of medical science have had to go to Albany to plead for the passage of a law for the registration of all who practice medicine in this State Nothing could be more reasonable, and nothing could be less likely to be criticized adversely by any man or woman with the training and knowledge requisite if such practice is not to endanger the public health and life The real doctors, how-

to base its decision upon the same kind of legal evidence as that which must be made the basis of a finding by a court. The act provides that the committee must determine charges "upon their merits." "If by unanimous vote the practitioner is found guilty of such charges or any of them, said committee shall transmit to the Regents the record, findings and determination wherein and whereby such practitioner has been found guilty, and their recommendation, and the Regents after due hearing shall in their discretion execute an order accepting or modifying such determination of said committee." If the practitioner is found not guilty, said committee shall order a dismissal of the charges and the exoneration of the accused." Furthermore, the committee has power to suspend, reprimand or otherwise discipline the accused doctor in accordance with the provisions of the act. If the Board of Regents adopts the adverse finding of the committee, the accused still has additional redress. He may then "have an order of certiorari for the purpose of reviewing such determination returnable before the appellate division of the third judicial department." This is in the nature of an appeal from the finding both of the grievance committee and of the Board of Regents. Thus, the rights of the doctor are amply safeguarded and protected.

The committee has power further in "any controversy between two or more physicians, or between a physician or physicians and another person," where the parties to the controversy "agree to submit to arbitration" to act as arbitrator in said controversy, and the decision of said committee upon such arbitration shall be final, and where the same orders the payment of a sum of money, the same may be docketed as a judgment of a court of record and enforced as such judgment, provided the terms of the arbitration include such provision."

Thus, there is set up machinery similar in all essential principles to the grievance committees of the various bar associations throughout the State by which the legal profession is regulated and controlled. These grievance committees, as is now well known by the public, act fairly and impartially upon charges preferred against lawyers. Their work is of benefit not only to the lawyers, but to the public, it insures that the aggrieved client may have his grievance promptly and fairly considered and decided, it also insures to the accused lawyer a prompt and fair determination not attended by the unpleasant and damaging features of malicious publicity. No doubt as a result of these lawyers' grievance committees, there are at the present time few malpractice actions instituted against lawyers. It is hoped and believed that the doctors' grievance committee will lessen or greatly tend to lessen the number of malpractice suits now instituted. The lawyers' grievance committees not only are

of benefit to the individual aggrieved client and the lawyer, but their work has greatly strengthened public confidence in the legal profession. The doctors' grievance committee should do the same thing for the profession of medicine.

It has oft times been said that the doctors are not willing to clean their own house and are not sufficiently vigilant to discipline their erring brethren or remove them from the practice of a profession for which they have shown themselves unfit. The proposed grievance committee is certainly an answer to those who make these accusations. It is the best evidence that the doctors are ready, willing and able to set their own house in order. It is an assurance to the laity that the medical profession is unwilling to tolerate the continuance in their midst of those who have shown themselves lacking in those professional standards which are the basis of confidence in the profession.

This machinery providing for a grievance committee has been thoroughly considered from every point of view, it is the result of the matured deliberations of the doctors and of the various public officials who have considered it. The writer has heard no good argument urged against it and the arguments in favor of it have not been and it is believed cannot be satisfactorily answered.

One of the salutary provisions of the proposed act is that by which prosecutions for its violation, except in counties having a population of more than 500,000, are to be conducted by the Attorney General and may be prosecuted before a court of special sessions without the necessity of an indictment or a trial before a petty jury. The advantages of this are apparent. In small communities it often becomes difficult or embarrassing for a local district attorney to prosecute one with whom he may personally be acquainted. The same considerations sometimes operate in the deliberations of grand and petty juries.

Furthermore, the bill provides that the regents may "appoint not less than five or more than seven inspectors under the direction of the secretary of the board of medical examiners to investigate promptly and thoroughly such violations and to procure where possible legal evidence of the same for prosecution of the offenders." Not only may these inspectors be used in that way, but "upon application of the committee on grievances to the secretary of the board of medical examiners the services of an inspector or inspectors may be furnished for making necessary investigations for said committee."

The machinery thus provided for prosecution of unlicensed practitioners and for assisting the grievance committee in properly ascertaining the facts is an important and vital part of the bill. Having provided the machinery, it was necessary to provide the funds with which to operate it. This has been done in part through the means

Chairman, Committee on Legislation

HEARING ON THE PRACTICE OF MEDICINE ACT

A hearing on the Practice of Medicine Act was held in the Capitol at Albany on Wednesday afternoon, March 3, and lasted three and a quarter hours. Its brevity was in marked contrast with the length of the hearings in previous years, but a recent hearing on the chiropractor bills which lasted eight hours had previously given the cultists the opportunity to set forth their views at length.

The opponents of the bill were heard first. The only opposition from a medical source came from Rensselaer County, but a second speaker from that county gave the bill his hearty support. The principal opposition to the bill came from the chiropractors. Judge Vander Zee, their attorney, said that this was the fourteenth successive year that the chiropractors had come before the Legislature and asked for recognition. He argued that the practice of medicine means the giving of drugs internally and the performance of surgical operations. He said that the proposed law would prevent the administration of home remedies and the giving of emergency relief, and he seemed unaware that both of these practices are permitted by the bill. He admitted that the chiropractors were violating the law every day. He estimated that there were between 3,000 and 4,000 chiropractors in New York State, who were patronized by two million patients. He said that the Practice of Medicine bill was good and that he would support it with the addition of the two words "and chiropractors" to the list of those who were exempted from the provisions.

The pastor of a church described two cases where he had introduced a chiropractor who had cured them, and he said that chiropractic treatment had twice cured him of hiccoughs. He argued that all persons should have a right to take the treatment if they wanted it.

Mr Lyndon Lee, ex-president of the New York State Chiropractic Society, said that if a man studied medicine he could not practice chiropractic so efficiently as he could if he had chiropractic training only, for the physician's theory of disease was opposed to that of the chiropractor.

A representative of the naturopaths said that the State Society had 406 members, who wished to get recognition for all cults. The opponents of the bill used an hour in the presentation of their case and then proponents were also given

an hour under the leadership of Dr H L K. Shaw, Chairman of the Committee on Legislation. Dr Wendell C Phillips, President-Elect of the American Medical Association, spoke of the education of physicians at the present time. Dr Van Etten, President of the Medical Society of the State of New York, described the method by which the bill was drafted and emphasized the fact that it was supported by the State Medical Society.

Dr Louis I Harris, Commissioner of Health of the City of New York, said that his official duty was to protect the health of six millions of inhabitants of the city and that he must have the help of a body of medical men who were competent. He said he frequently received complaints from persons who claimed they had been improperly treated, especially by cultists. He closed by saying that if it were true that two million persons patronized illegal practitioners, that fact would be an evidence of an increased need of public education in medical matters.

Mr Homer Folks, Secretary of the State Charities Aid Association, said that his association had done state-wide work among needy children for half a century and that he was constantly compelled to secure medical relief for them. He argued that public opinion demanded that he get only competent medical assistance for the children. He said that the present law had been examined by the lawyers of the Association and found entirely legal and practical. His Association would therefore support it heartily.

A woman worker from the State Charities Aid Association pleaded for the adoption of a high standard of medical practice for the benefit of pregnant woman, all of whom should receive advice throughout the period of pregnancy.

Mr John A Kingsbury spoke on the lengthening of life in recent years chiefly as the result of medical knowledge, and said that a further lengthening depended on the skill and knowledge of physicians who were interested in public health.

Dr Samuel J Kopetzky, ex-President of the Medical Society of the County of New York, argued for the need of a high basic scientific education for all who aspired to practice any healing art. He cited the use of X-rays as an example of what many ignorant healers wished!

ever, have learned from sad experience in this and other States that too many legislators are prone to show a childish faith in quacks and to legalize the doing of things in ignorance which should be done only by the possessors of at least a part of the available information

"Already our own lawmakers have licensed one great group of practitioners who prove themselves charlatans by using only one remedy for all maladies. A second great group of much the same quality sees in the Webb-Loomis bill an attempt to 'put them out of business.' So it is, in one way, though not in another

"They have against them the reputable doctors and surgeons in the State, but the latter cannot be sure of success while our legislators listen

with seeming patience to such statements as that even a blacksmith should be allowed to treat the sick who desire his ministrations. They still have to learn that diagnosis, none too certain at best, is the only preparation for sound treatment, and that at its worst—by blacksmiths, masseurs and the like—it can be less than murder only by lack of intention to kill

'Of course, 'wonderful cures,' some of them real in the sense that recovery has followed treatment, can be instanced for every strange cult, and that is vindication for quackery in the estimation of those who forget the powers of suggestion in some cases and that many human maladies need only the 'healing power of nature''"

FRACTURED ELBOW—IMPAIRMENT OF FUNCTION

In this action it was charged that the physician who was engaged to attend and treat a fracture which the infant plaintiff had sustained to her left arm was negligent and careless so that the fractured parts improperly and imperfectly knitted, causing the arm to become crooked, thereby permanently depriving the child of the full and normal use of such arm

Upon the day of the injury the injured child was brought to the physician's office, and upon examination he found an extensive fracture of the elbow. At this time the arm had been given emergency treatment by some other physician, and the arm was in flexion and bandaged with a wet dressing. The child was sent to the hospital by the defendant, where he removed the bandages and by careful manipulation reduced the fracture under a general anaesthesia. X-rays were thereafter taken, which showed that the bones were not in perfect apposition. The arm was thereupon further manipulated and a second series of X-rays taken, which showed better position of the displaced parts. Thereafter, the arm was further manipulated and a third series of X-rays taken, which showed improved position in the reduction of the fracture. The arm was put up in flexion in a plaster cast. For the next three days the patient was seen by the defendant and thereafter the patient was under the care of his family physician. About ten days

after the injury the defendant, with the family physician, removed the cast and upon examination found the fractured parts in satisfactory position. The further care of the child was left to the family physician, with advice from the defendant as to passive motion and massage. About a month later the child was returned to the defendant physician, and upon examination at this time he found a marked limitation of motion of the elbow, flexion limited to 80% and extension to 110%, and thereupon suggested baking and massage at his own office. The patient received such treatment about three times a week for the next four weeks. The baking and massage were done by the defendant's nurse under his direction and supervision or by the defendant himself. The patient was last seen by the defendant about two months after the fracture and after the patient had had four weeks of baking and massage. When last seen by the defendant, there was a light increase in motion. The patient was thereafter not seen by the defendant nor any further treatment rendered by him. Upon rendition of his bill to the parents of the injured child, which was never paid, the defendant was met with the action of alleged malpractice.

After the action had remained on the calendar for some period of time and when about to be reached for trial, the plaintiff's attorney consented to the discontinuance of the action.

HEARING ON THE PRACTICE OF MEDICINE ACT

A hearing on the Practice of Medicine Act was held in the Capitol at Albany on Wednesday afternoon, March 3, and lasted three and a quarter hours. Its brevity was in marked contrast with the length of the hearings in previous years, but a recent hearing on the chiropractor bills which lasted eight hours had previously given the cultists the opportunity to set forth their views at length.

The opponents of the bill were heard first. The only opposition from a medical source came from Rensselaer County, but a second speaker from that county gave the bill his hearty support. The principal opposition to the bill came from the chiropractors. Judge Vander Zee, their attorney, said that this was the fourteenth successive year that the chiropractors had come before the Legislature and asked for recognition. He argued that the practice of medicine means the giving of drugs internally and the performance of surgical operations. He said that the proposed law would prevent the administration of home remedies and the giving of emergency relief, and he seemed unaware that both of these practices are permitted by the bill. He admitted that the chiropractors were violating the law every day. He estimated that there were between 3,000 and 4,000 chiropractors in New York State, who were patronized by two million patients. He said that the Practice of Medicine bill was good and that he would support it with the addition of the two words "and chiropractors" to the list of those who were exempted from the provisions.

The pastor of a church described two cases where he had introduced a chiropractor who had cured them, and he said that chiropractic treatment had twice cured him of hiccoughs. He argued that all persons should have a right to take the treatment if they wanted it.

Mr. Lyndon Lee, ex-president of the New York State Chiropractic Society, said that if a man studied medicine he could not practice chiropractic so efficiently as he could if he had chiropractic training only, for the physician's theory of disease was opposed to that of the chiropractor.

A representative of the naturopaths said that the State Society had 406 members, who wished to get recognition for all cults. The opponents of the bill used an hour in the presentation of their case and then proponents were also given

an hour under the leadership of Dr. H. L. K. Shaw, Chairman of the Committee on Legislation. Dr. Wendell C. Phillips, President-Elect of the American Medical Association, spoke of the education of physicians at the present time. Dr. Van Etten, President of the Medical Society of the State of New York, described the method by which the bill was drafted and emphasized the fact that it was supported by the State Medical Society.

Dr. Louis I. Harris, Commissioner of Health of the City of New York, said that his official duty was to protect the health of six millions of inhabitants of the city and that he must have the help of a body of medical men who were competent. He said he frequently received complaints from persons who claimed they had been improperly treated, especially by cultists. He closed by saying that if it were true that two million persons patronized illegal practitioners, that fact would be an evidence of an increased need of public education in medical matters.

Mr. Homer Folks, Secretary of the State Charities Aid Association, said that his association had done state-wide work among needy children for half a century and that he was constantly compelled to secure medical relief for them. He argued that public opinion demanded that he get only competent medical assistance for the children. He said that the present law had been examined by the lawyers of the Association and found entirely legal and practical. His Association would therefore support it heartily.

A woman worker from the State Charities Aid Association pleaded for the adoption of a high standard of medical practice for the benefit of pregnant women, all of whom should receive advice throughout the period of pregnancy.

Mr. John A. Kingsbury spoke on the lengthening of life in recent years chiefly as the result of medical knowledge, and said that a further lengthening depended on the skill and knowledge of physicians who were interested in public health.

Dr. Samuel J. Kopetzky, ex-President of the Medical Society of the County of New York, argued for the need of a high basic scientific education for all who aspired to practice any healing art. He cited the use of X-rays as an example of what many ignorant healers wished

to use, but which was actually as dangerous as a knife

Dr Augustus Downing, Assistant Commissioner of Education, who has been active for a score of years in maintaining and raising the standards of medical practice, argued for annual legislation. He said that as a result of it sixteen hundred dentists who were practicing illegally had left the state. He explained some of the requirements of the bill, and answered those who had been misinformed about the contents.

Dr Matthias Nicoll, Jr, State Commissioner of Health, described difficulties he had in enforcing contagious disease prevention, and argued in favor of a bill which would discipline physicians as well as exclude those who are incompetent to recognize or treat scarlet fever and other contagious diseases.

Mr Lyndon Lee, in rebuttal of the doctors arguments, said that it was not fair to suggest that the chiropractors be required to study in a medical college, because no college would receive them. He had received letters to that effect from the Deans of some of the colleges.

Mr Lloyd P Stryker, counsel for the Medical Society of the State of New York, closed the hearing in a stirring speech. He said that

the law required a doctor to give treatment in accordance with the state of medical knowledge, and to be neither ahead or behind the times. He quoted from the sworn testimony of leading cultists in cases against chiropractors to show that they said that it was not necessary for a practitioner of that cult to know what ailed a patient. One of the advocates of the cultists interrupted the speaker and said that he wanted to prevent that kind of practitioner from practicing. Mr Stryker said that the question at issue was not the relative merits of different classes of healers, but whether or not any one should be allowed to practice medicine without preliminary scientific education. The cults violated this principle when they sought recognition by means of a waiver clause. The value of any particular kind of scientific service could not be decided by a popular vote, any more than questions in astronomy could be decided by a canvass of popular beliefs. The Practice of Medicine bill was directed against all fakers and incompetents in medicine.

The general impression among the doctors that attended the hearing was that it set a new standard by the manner in which it was conducted and by the effectiveness of the addresses.

LEGISLATIVE BILLS

Although the Legislature has been in session for nearly two months, new bills affecting public health are still being introduced and original ones amended. It is, therefore, difficult to print an accurate estimate of legislative affairs. However, the Committee on Legislation are sending weekly bulletins to the Chairmen of the Legislative Committee of the County Society and these contain summaries of the medical bills and the actions taken on them. The three bulletins that have been issued are printed in this department.

A hearing on the Chiropractic Bill was held on February 24, and lasted all the afternoon and evening. The comments on this hearing contained in bulletin number three express the feelings of the physicians who were present.

A hearing on the Jenks Podiatry bill, assembly Int. 417, was held on the morning of March third. The chiropodists asked that they be allowed to use the title of doctor on the ground that people generally already address them as doctor. They wish to add the word "of podiatry" after the word doctor. The representative of the State Medical Society protested against their request, but Dr Downing of the Department of Education was inclined to grant their request, provided the words "of podiatry" were added in type as large as that used with the word "doctor."

Also a hearing was held on Assembly Introductory bill, number 726, the Ricca bill, which would license the makers of orthopedic appliances. The proponents of the bill propose to establish a board of "Orthopedistry" which would license the makers of trusses and other orthopedic appliances. But since the word orthopedistry resembles orthopedics, which is a medical specialty, the backers of the bill had withdrawn it and substituted another in which the word "Bandagistry" was used in place of orthopedistry. The makers of braces and trusses claim that the word bandagistry is applied to their work in Europe and that they wish to be known as bandagists.

When the physicians that were at the hearing opposed the bill on the ground that it would permit the bandagists to make diagnoses, the bandagists said they would be willing that a clause be inserted forbidding them to make diagnoses, or to prescribe an apparatus except on the prescription of a physician.

The usefulness and need of the bill are extremely doubtful. It seems to be an attempt of another group to secure special privileges under the plea of purifying its ranks and raising its standard of practice.

Another cult or specialty or mode of treatment has been adopted into the family of fifty-

seven cults listed by the Department of Health of New York last Spring. Senate bill, introductory 782, is on the subject of oralgys. An oralgyst would seem to mean a throat and mouth specialist, but according to the bill a person practices oralogy "who holds himself out as being able to prevent, diagnose, treat or eliminate disease conditions." Only licensed physicians or dentists can become oralogysts. The list of

studies to be pursued in order to obtain the title ends with the subject of spinal analysis. The bill would seem to represent an attempt of unsuccessful dentists to secure a permit to practice chiropractic in form if not in name.

Three Legislative Bulletins have been sent to the Chairmen of the Legislative Committees of the County Societies.

LEGISLATIVE BULLETIN No 1

February 17, 1926

No important action was taken during the week on any of the bills reported to you in our last communication. Several new bills in which you will be interested have been introduced in the meantime.

IN SENATE

OSTEOPATHIC FIELD OF PRACTICE

Senate Introductory No 549—A bill introduced by Mr Gibbs, would amend the Public Health Law in relation to the practice of osteopathy, by adding a new clause which would give osteopaths authority to perform minor operations and to administer narcotics for the relief of suffering, anaesthetics, antiseptics, vaccines and anti-toxin, the anaesthetics to be used in minor operations. The more recently graduated osteopaths have, for several years, been considering asking for this amendment. Let us know your opinion upon it.

IN ASSEMBLY

BOARD OF TRUSTEES OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

Assembly Introductory No 725—concurrent Senate Introductory No 532—A bill introduced in the Assembly by Dr Lattin is an amendment prepared by our Society making possible the organization of a Board of Trustees. This amendment was introduced in accordance with action taken by the House of Delegates at the annual meeting in Syracuse.

FITTERS OF ORTHOPEDIC APPLIANCES

Assembly Introductory No 726—concurrent Senate Introductory No 582—A bill introduced in the Assembly by Mr Ricca, would amend the Public Health Law by adding new matter under which those persons who sell and fit orthopedic appliances would be licensed by the State and operate under a special board of their own. Anybody reading this bill can readily see that if this provision were enacted into law, those who build, fit and sell appliances would be authorized to apply them on their own initiative, and thereby would, of course, assume to diagnose the condition which they attempt to remedy. You must

certainly have an opinion with regard to this bill. Let us have it.

Assembly Introductory No 892—A bill introduced by Mr Miller would amend the Workmen's Compensation Law in relation to occupational disease arising out of employment. This is an important bill, because men sometimes discover that having left an occupation for a year or more, that they are victims of a disease which the physician diagnoses as having been caused by conditions in the previous occupation. Study this bill carefully and give us an opinion on it.

Assembly Introductory No 690—A bill introduced by Mr Meegan would amend the Public Health Law in relation to the definition of practice of medicine. Comment on this bill was made on page 5 of our previous communication.

PRACTICE OF MEDICINE BILL

Our Medical Practice Act has been introduced by Dr Loomis, and will bear the number Assembly Introductory No 955. Printed copies of this bill will be available in four or five days and you will get a copy with the next bulletin.

COMMITTEE HEARINGS

- February 17th—Assembly Int No 389—Health Officers, local (Lattin)
Assembly Int No 657—Health Law, Dentistry (Lattin)
Assembly Int No 725—State Medical Society, Board of Trustees (Lattin)
February 24th—Assembly Int No 65—Workmen's Compensation (Miller), (conc Senate Int No 35), Medical Care (Truman)
Assembly Int No 153—Health Law, Chiropractic (Esmond)
Assembly Int No 331—Workmen's Compensation, eye, rules (Miller)
Assembly Int No 364—Workmen's Compensation, vision tests (Hofstadter)

LEGISLATIVE BULLETIN No 2

February 24, 1926

We are pleased to say that in response to our urgent solicitations for opinions, we have to date had comments from at least a dozen men and Medical Societies on more than a dozen bills. This is very encouraging, and we hope that the number may increase materially in response to this, our second bulletin.

Since our last communication there have been introduced to the Legislature the following bills in which we are interested

THE PRACTICE OF MEDICINE BILL

Assembly Introductory No 955—concurrent Senate Introductory No 717—An amendment to the Medical Practice Act. This is the bill in which we are vitally interested. It is being sponsored in the Assembly by Dr Loomis from Delaware County, who is very enthusiastically "selling" the bill to the members of the Assembly individually.

DENTAL BOARD

Assembly Introductory No 917—concurrent Senate Introductory No 688—A bill introduced by Dr Lattin would amend the Public Health Law concerning the practice of dentistry, allowing for an increase in the salary of the secretary of the Dental Examining Board and providing that the monies collected through fees, fines and penalties shall be paid to the Regents of the University, and be available, together with appropriations that may be made from time to time by the Legislature, for the payment of salaries and expenses connected with the activities of the Examining Board—and the fine for practicing without a license is increased from \$50.00 to \$100.00.

PRIVATE HOSPITALS

Assembly Introductory No 919—concurrent Senate Introductory No 741—A bill introduced by Mr Hofstadter. A copy of it is being sent you because it aims to correct a very serious matter. It would make it a misdemeanor for any one to obtain board, medical supplies or nursing at a privately owned hospital or sanitarium by means of any false pretense or with an intent to defraud. This bill your Committee will certainly support unless there are special reasons for opposition of which we are not aware.

TESTING EYES OF SCHOOL CHILDREN

Assembly Introductory No 937—A bill introduced by Mr Eberhard. This bill has not yet been introduced in the Senate. It would amend the Education Law authorizing the em-

ployment of optometrists or oculists to make eye tests of pupils attending the public schools. A copy of the bill is being sent, that you may read it over carefully and advise the Committee immediately with your opinion as to whether we should support or oppose the bill.

CHAUFFEURS' EXAMINATIONS

Assembly Introductory No 948—A bill introduced by Mr Landau. This bill has not yet been introduced in the Senate. It would require that all operators or chauffeurs be examined by a physician to determine if they are physically fit to operate a motor vehicle, certificate thereof to be attached to application for license.

X-RAY TREATMENTS

Assembly Introductory No 1025—concurrent Senate Introductory No 709—A bill introduced by Mr Landau would amend the Public Health Law by defining the practice of medicine to include the application of X-ray treatment to any person. This is a very important bill, and it is hoped that you will read the enclosed copy very carefully and then give us your reaction. In New York City at the present time the matter of licensing X-ray operators is receiving a great deal of attention. It is, therefore, a very opportune time for the State to be considering it.

INSPECTORS OF SCHOOL CHILDREN

Assembly Introductory No 1042—A bill introduced by Mr Rice. This bill has not yet been introduced in the Senate. It would amend the Education Law in order to provide that where two physicians are employed as inspectors of schools, each devoting one-half of his time to the duties, the money apportioned by the State for one full-time inspector shall be divided between them in accordance with the time devoted. There may be no objection to dividing the money apportioned for a full-time school inspector between two or more physicians who will devote as much time to the work as a single man might, but there is, however, a condition produced thereby which should receive the attention of the medical men—that is, that while the bill calls for a full-time inspector, it would mean that one man should devote his entire time during the school hours of the day to the work of the school. It does not prevent him from practicing medicine in other parts of the twenty-four hours, and if the school hours are divided between two or more physicians, of course, each in turn will have more time for continuing the practice of medicine.

LEGISLATIVE BULLETIN No 3

HEARING ON THE CHIROPRACTIC BILL

March 2, 1926

Last Wednesday, February 24th, the Esmond Chiropractic Bill was discussed before the Assembly Committee on Public Health. The following organizations and persons appeared with us in opposition to the bill:

From the Department of Education, Dr Downing
From the Department of Health, Dr Nicoll
American Association for Medical Progress
State Charities Aid Association
Bowling Green Neighborhood Association
East Harlem Health Center
Association for Improving the Condition of the Poor, New York City
Federated Neighborhood Association, New York City
Henry Street Settlement, New York City
American Social Hygiene Association
New York Tuberculosis and Health Association
Westchester County Tuberculosis Association
Albany County Tuberculosis Association
Tompkins County Tuberculosis Association
President of the Osteopathic Society
Assemblyman Hall, who came at the request of the physicians of Orange County

The usual persons spoke in favor of the bill—namely, Mr Esmond himself, who took up about half the time allowed the opposition. His methods were very objectionable to the chairman and members of the Committee. He heckled every opponent by asking leading questions which he alone was willing to answer. His methods were finally so objectionable that Dr Lattin offered him the gavel and asked him if he did not want to preside.

The others who spoke in favor of the bill, were

Past-President Lee of the State Chiropractic Association

Representatives of the Chicago and New York Schools of Chiropractic

Mr Vanderzee, their counsel

It is hardly possible that the bill will come out of Committee this year.

HEARING ON WORKMEN'S COMPENSATION BILLS

On February 24th there were hearings before the joint Senate and Assembly Committees on Labor and Industry on two important compensation bills—namely, the Eye Bill (Assembly Introductory No 331—Miller) and the Medical Reorganization Bill (Assembly Introductory No 65—Miller). The labor unions brought strong delegations in opposition to both of these bills. Dr Snell of Rochester and Dr Bennett of Buffalo appeared in favor of the Eye Bill and offered

amendments which will be incorporated and probably make possible the passage of the bill this year, but the opposition to the Medical Reorganization Bill was so powerful that there is grave doubt as to whether it can be amended satisfactorily this year.

TRUSTEE BILL

Our Trustee Bill (Assembly Introductory No 725—Senate Introductory No 532) has been passed by the Assembly and referred to the Senate.

We are preparing for hearings on March 3rd on the following bills:

CHIROPODISTS AND THE TITLE OF DOCTOR

Assembly Introductory No 417—Jenks—concurrent Senate Introductory No 552—Karle)—Use by chiropodists of the title "doctor." The chiropodists ask to be permitted to display at their offices their names in the following manner:

"Dr John Doe, Chiropodist"

The Department of Education has told them that they will be satisfied to permit the chiropodists to use such display, providing they use the same size letter for the name, title and word "chiropodist." They refuse to approve of a display, which would show "Dr John Doe" in a larger type than the word "chiropodist."

LICENSING BRACE MAKERS

Assembly Introductory No 726—Ricca—concurrent Senate Introductory No 582—Hastings—(see bulletin No 1 for discussion). We have had many letters from orthopedists urging us to oppose this bill on the ground that it would permit manufacturers of splints to make their own diagnoses.

X-RAY DIAGNOSES

Assembly Introductory No 1025—Landau—concurrent Senate Introductory No 709—Carroll—(see bulletin No 2 for discussion). Mr Landau advises us that there was a mistake in drafting the bill. He did not mean to regulate X-ray treatment, but X-ray diagnosis, and he will so amend the bill at the hearing tomorrow. He also agrees that it is not a wise move on his part to endeavor to have the definition of the practice of medicine changed so as to include diagnosis by X-ray, and will try to add his amendment to another part of the law.

PRACTICE OF MEDICINE BILL

Assembly Introductory No 955—Loomis—concurrent Senate Introductory No 717—Webb—Since this bill has been printed, Dr Stanton of Schenectady offered a serious objection to the wording in several places. He suggested different wording which was accepted by both intro-

ducers and the bill will be so amended immediately. Copy of these amendments were sent you in a letter two or three days ago.

We have just learned that the osteopaths will appear in opposition to our bill on the ground that we have shown no inclination to support them in their efforts to secure permission to use anæsthetics. The only other definite opposition that we are aware of, will come from the chiropractors.

The following bills have been introduced during the last week.

IN SENATE

Senate Introductory No 757—introduced by Mr Byrne. This bill has been introduced annually for the last several years. It is opposed by the Department of Health and charity organizations. We wish you would look over the enclosed copy and tell us whether you think we should support it.

ORALOGY BILL

Senate Introductory No 782—introduced by Mr Bouton. A copy of this bill is being sent you. Read it over carefully. It is one of the most ridiculous bill that has been introduced this year. Note particularly the subjects that examinations must be passed in before the degree will be granted, then note the definition of the term "oralogy," and observe, also, that only graduate physicians and dentists are eligible to the examinations, and that whoever successfully passes the examinations will be eligible to the degree of doctor of public health and may use the initials "D P H" in connection with his name. Suspicion is immediately aroused, when it is noted that among the list of studies to be undertaken is spinal analysis.

IN ASSEMBLY

SALE OF EYE GLASSES

Assembly Introductory No 1051—Mr Meehan reintroduced his bill of last year, which would provide that eye glasses, spectacles and lenses shall not be sold at retail unless licensed physician or optometrist is in charge of counter or booth. Last year we took a neutral position with regard to this bill. We appreciate that harm can come from permitting young people to fit themselves with eye glasses, but we also appreciate that people with presbyopia alone can frequently fit themselves very satisfactorily. The bill also specifies lenses, probably meaning hand reading glasses.

WORKMEN'S COMPENSATION

Assembly Introductory No 1073—concurrent Senate Introductory No 759—This is a bill introduced by the Department of Labor and Industry, and is identical with the latest print of Mr Miller's bill, Assembly Introductory No 331. It was included with those receiving a hearing on February 24th.

ANÆSTHETISTS IN HOSPITALS

Assembly Introductory No 1097—A bill introduced by Mr Grossman, which would amend the Public Health Law by providing that physicians only shall administer an anæsthetic in hospitals. Mr Grossman seems to have originated this bill himself, attributing some influence to a friend. He says that it is his opinion that administering an anæsthetic is a serious undertaking, and that nurses should never be allowed to do it. Already opposition to this bill is appearing. Won't you write us your instructions immediately?

THE ANNUAL MEETING

THE ANNUAL MEETING

The Annual Meeting of the Medical Society of the State of New York will be held on March 29 to April 1, inclusive, in the Waldorf-Astoria, Thirty-fourth Street and Fifth Avenue, New York City. This well known hotel is ideally situated and arranged for the meeting and nearly the whole space of the second floor will be occupied by the Society. The meeting rooms of the exhibits open off from spacious corridors, and abundant opportunities are offered for meeting one's friends and holding informal conversations and conferences.

The Hotel Waldorf-Astoria, where the Medical Society of the State of New York will meet.

The four days of the meeting will be filled with features so fully that one will not need to leave the Hotel during the entire session. However, the hotel is within easy access of hospitals and clinics where one may see the latest diagnostic and therapeutic procedures exemplified. Possibly some of the doctors will wish to visit the theatre district, which is within easy access of the hotel.

The physical provisions for the meeting are more nearly perfect than those for any previous meeting.

The rooms are on the second floor, within easy walking access from the main entrance. The facilities of the hotel are at the disposal of the members and their friends.

Other meetings will also be held in the Waldorf-Astoria Hotel. The State Laboratory Association will convene and there are always other medical organizations who take the opportunity to hold their annual meetings while the physicians are convened.

The Registration Booth will be in the corridor at the head of the main staircase, where no one can possibly miss it. Be sure to get a lapel button and wear it.

The Registration Booth will also be the headquarters for information. There the press reporters may obtain data concerning the members and the meetings.

The programs of the Scientific Sessions are printed on page 283 of this issue and will be found to be of unusual interest and practical value.

The Syphilis Exhibit and lectures on Thursday will be modelled after the exhibit on Tuberculosis held on the closing day of last year's sessions. That exhibit set a new standard for an exhibition on a special subject, but profiting by the experience the Scientific Committee have set out to beat its own record.

The program of the exhibit is printed on page 289 of this JOURNAL. Specimens and charts will be exhibited and a complete picture of syphilis and every part of the body will be shown as far as possible. At least fifteen distinct phases of pathology will be shown, including the congenital type of paresis, and syphilis of the eye and ear. Among the institutions which will have exhibits and demonstrations are the Bellevue, the City Mount Sinai, and the New York Hospitals, the Rockefeller Institute, the City Department of Health, the Vanderbilt Clinic, the Dental College, and the New York State Department of Health.

Demonstrators will be present during the morning to explain the specimens and lectures will be given during the afternoon.

All come prepared to spend Thursday viewing the exhibit.

THE COMMERCIAL EXHIBITS

Every physician who attends the Annual Meeting of the Medical Society of the State of New York is deeply interested in the tools and equipment with which he works. He wishes to see the newest products, to get acquainted with the exhibitors, to handle the outfits and to become familiar with the newest phases of mechanical appliances. The visiting doctors will find many of their questions answered by the exhibit-

ors who have taken spaces on the same floor with the meeting halls.

Sixty exhibitors will show their products from booths which are readily available to all the doctors as may be seen by reference to the chart on page 270. The following descriptions of their products have been furnished by the exhibitors themselves.

LIST OF EXHIBITORS

	Booth Number		Booth Number
Abbott Laboratories, New York, N. Y.	6	J. B. Lippincott Company, Philadelphia, Pa.	22
Allison Co., N. Y.	19	McIntosh Electrical Corp., Chicago, Ill.	36
American Medical Association	54	Merrell Soule Company, Syracuse, N. Y.	15
Anglo-French Drug Co., New York, N. Y.	16	Herman Metz, New York, N. Y.	35
D. Appleton & Company, New York, N. Y.	51	E. B. Meyrowitz, New York, N. Y.	9
Bausch & Lomb, Rochester, N. Y.	55-56	C. V. Mosby Company, St. Louis, Mo.	47
Becton, Dickinson Co., Rutherford, N. J.	20-21	V. Mueller & Company, Chicago, Ill.	3
Harold Bennett, New York, N. Y.	27	Multiplex Display Fixture Company, St. Louis	70
Frank S. Betz, New York, N. Y.	62	Mutual Pharmacal Co., Syracuse, N. Y.	37
P. Blakiston's Sons & Co.	38	Thomas Nelson & Sons, New York, N. Y.	23
Cambridge Instrument Co., Ossining, N. Y.	7	E. L. Patch, Stoneham 80, Boston, Mass.	41-42
Cameron Surgical Specialty Co., Chicago, Ill.	48	Praus American Instrument Co., New York	31
C. P. Chemical Company, New York, N. Y.	64	James Picker, Inc., New York, N. Y.	2
F. A. Davis Company, Philadelphia, Pa.	26	S. Pongho & Co., New York, N. Y.	59
Deshell Laboratories, Brooklyn, N. Y.	18	Prometheus Electric Co., New York, N. Y.	34
De Vilbiss Manufacturing Co., Toledo, Ohio	50	Radium Emanation Corp., New York, N. Y.	16
H. T. Dewey & Sons, New York, N. Y.	11	Sanborn Company, Cambridge, Mass.	24
Dry Milk Company, New York, N. Y.	46	Sanka Coffee Corporation, New York, N. Y.	57
Fairchild Bros. & Foster, New York, N. Y.	33	W. B. Saunders Company, Philadelphia, Pa.	43
H. G. Fischer & Co., Inc., Chicago, Ill.	60	J. S. Sklar, Brooklyn, N. Y.	13
Foregger Corporation, New York, N. Y.	40	C. M. Sorensen, Long Island City, N. Y.	28-29
Hanovia Chemical Company, Newark, N. J.	10	Spencer Lens Company, Buffalo, N. Y.	63
Harold Surgical Corp., New York, N. Y.	17-39	Standard X-ray Sales Corporation, New York	8
Paul Hoeber, New York, N. Y.	12	Thompson Plaster X-Ray Co., Inc., New York	53
Hoffmann-La Roche Chemical Works, N. Y.	30	George Tiemann, New York, N. Y.	14
Horlick's Malted Milk Co., Racine, Wis.	32	Victor Electric Company, Chicago, Ill.	45
Hospital Supply Company, New York	71	Wappler Electric Co., Long Island City, N. Y.	1
Hynson, Westcott & Dunning, New York	25	Walnut Castle Company, Rochester, N. Y.	49
Kalak Water Company, New York, N. Y.	52		
K. & B. Electric Equipment Co., New York	4-5		
Laboratory Products, Cleveland, Ohio	44		

BOOKS

Booth 54—The American Medical Association, Chicago, Illinois, will have on exhibit a complete display of all American Medical Association publications. In addition to the Journal (American and Spanish Editions) the A. M. A. will show the several Archives in the various branches of medicine including the new Archives of Pathology and Laboratory Medicine, American Journal of Diseases of Children and also Hygiene and numerous pamphlets and reprints of spe-

cial interest to Physicians and Health Workers.

The official American Medical Association emblem will also be shown in the regular radiator style and combined with the Signaphore.

Physicians will be especially interested in the exhibit of the A. M. A. for it is their own organization. A visit to the booth will reveal the comprehensive activities of the national medical organization and its service to the individual physician.

Booth 51—D. Appleton & Company, who in 1925 celebrated its hundredth anniversary, has on display a number of its medical publications. Among these appear the monumental work of Frederick Forchheimer in a new edition which is edited by George Blumer of Yale, also the Appleton series of Monographs on Gynecology and a number of Monographs on Surgery.

Such well-known texts as Holt's "Diseases of Infancy and Childhood," Osler's "Principles and Practice of Medicine," Rosenau's "Preventive Medicine and Hygiene," Keyes' "Diseases of the Genito-Urinary System," Williams' "Obstetrics," and many others are on display. These old and well known texts have been kept up by numerous revisions, so that they represent the latest advance in medicine.

Booth 38—P. Blakiston's Son & Co. present an exhibit of its complete list of Medical Books, including many new titles that have appeared within the last few months. Of special interest are the following books, all published this year, or late in 1925: Deaver's "Surgical Anatomy" (3 vols.), Greene's "Medical Diagnosis" (2 vols.), Riehl and von Zumbusch "Skin Atlas" (3 vols.), Fulkerson's "Gynecologic Urology," Potter's "Therapeutics," Enfield's "Radiography," Matthes' "Differential Diagnosis," and numerous other titles.

Booth 26—The F. A. Davis Company of Philadelphia will exhibit its publications, including the following:

The new, entirely rewritten edition of "Modern Ophthalmology" by James Moores Ball of St. Louis, Mo., in two large, handsome royal octavo volumes.

"Diseases of the Ear, Nose and Throat," by Harold M. Hays of New York.

A thoroughly modern work on "Gynecology, Medical and Surgical" by P. Brooke Bland of Philadelphia.

A new (6th) revised edition of "Diseases of the Stomach and Upper Alimentary Tract" by Anthony Bassler of New York.

"Feeding and the Nutritional Disorders in Infancy and Childhood," new (4th) revised and enlarged edition, by Julius H. Hess of Chicago.

These and many other important new books and new editions may be seen at Exhibit Booth No. 26.

Booth 12—Paul B. Hoeber, Inc. During the past year this house has added to its list an unusually large number of publications which seem destined to take their place as standard works. It will show its entire line, including the *Annals of Roentgenology* and the famous *Annals of Medical History*. It calls particular attention to the following of their new publications: Sachs and Hausman's "Nervous and Mental Disorders from Birth through Adolescence," "Henry Ford Hospital Report," Jackson's "Goiter," "Transactions of the Charaka Club," Stewart's

"Physiotherapy," Stewart's "Skull Fractures, Roentgenologically Considered," and the beautiful atlas by Lynch and Felsen on "Tumors of the Colon and Rectum."

There will also be shown some of its earlier outstanding publications, such as Tilney and Riley's "Form and Functions of the Central Nervous System," Elsberg's "Tumors of the Spinal Cord," Ruhrah's "Pediatrics of the Past," Kereley and LeWald's "Digestive Disturbances in Infants and Children, Roentgenologically Considered," Aschoff's "Lectures on Pathology," Gross's "Blood Supply to the Heart," Osgood's "Teeth and Jaws, Roentgenologically Considered," Pardee's "Clinical Aspects of the Electrocardiogram," etc.

As usual, this house will display a number of rare medical items.

Booth 22—J. B. Lippincott Company invites you to its special exhibit of important new publications of timely interest to the progressive physician. Outstanding new titles on display are Karsner's Textbook of Pathology, Craig's Parasitic Protozoa of Man, Foote's Diseases of the New-Born, Henderson's new translation of Meyer and Gottlieb's Experimental Pharmacology, Cushing and Bailey's Classification of the Tumors of the Ghoma Group, the new printing of Spalteholz's Anatomy, the Third Edition of Villiger's Brain and Spinal Cord, the Third Edition of Dennett's Simplified Infant Feeding, Van Leeuwen's Allergic Diseases, the year's cream of practical medicine in the International Clinics and our regular line of standard medical work.

Booth 47—The C. V. Mosby Company will exhibit standard texts and monographs. These will include the new edition of Crossen "Operative Gynecology," Horsley "Operative Surgery," Hirschman "Diseases of the Rectum," Sutton "Diseases of the Skin." Among the newer texts and monographs will be Duke "Allergy," Orr "Amputation," Adam "Asthma," Ryall "Operative Cystoscopy," Beattie and Dickson "Pathology," Mayo and Plummer "Thyroid Gland," Hamilton "Psychopathology."

The company will also show its line of special Journals, including *The American Journal of Obstetrics and Gynecology*, *The American Heart Journal*, *The American Journal of Syphilis* and *The Journal of Laboratory and Clinical Medicine*. Dr. E. E. Stillman will be in charge.

Booth 23—Nelson's Loose-Leaf Living Medicine is an international work on internal medicine, in eight volumes, including index volume, bound in three-quarter Persian morocco, and fully illustrated with charts, tables, microphotographs, roentgenograms, cardiograms, and photographs showing the actual clinical conditions which present themselves to the practitioner. There are, in addition, a large number of colored plates prepared especially for this work and representing the finest type of medical illustration.

There is furnished also to all subscribers free membership to the Nelson Service Bureau, which gives additional information on any and every subject in internal medicine

The splendid reception accorded medicine by the medical profession has induced the publishers to undertake the publication of a "Surgery," complete in seven volumes and Index Volume, which is now in preparation

Booth 43—W. B. Saunders Company, publishers, Philadelphia and London This company will exhibit a complete line of their publications

Of particular interest will be Young's new work on "Urology", Lihenthal's "Thoracic Surgery", Bickham's "Operative Surgery", Abt's work on "Pediatrics", Cabot's new work on the "Heart" Moynihan's new edition of "Abdominal Operations", Anders and Boston's "Medical Diagnosis", Palfreys "Art of Medical Treatment", Pratt and Bushnell's "Chest Diagnosis", thirteenth edition of "The American Illustrated Medical Dictionary", Boyd's "Surgical Pathology", Morse's "Biochemistry", and advance sheets of the new Mayo Clinic volume

ELECTRO-THERAPEUTICS

Booth 48—The Cameron Surgical Specialty Company will give clinical demonstrations of Transillumination, direct illumination, Electro-cauterization, and high frequency Cauterization with the Cauterodyne as applied to all phases of minor and major diagnostic, operative, and therapeutic procedure

Booth 60—H G Fischer & Co, Inc., of Chicago, Ill, will have a complete exhibit of the latest developments in electro-physiotherapeutic equipment. Special attention is called to the two radical departures from customary diathermy machine construction, as embodied in their two latest units Its large Senior Diathermy Cabinet is the most versatile equipment of its type, with a splendid range of power, and their new Portable Type "G" makes a wonderful all-around diathermy outfit for use in the office, operating room or patient's home

Booths 4-5—The K. & B Electrical Equipment Co will show the latest developments in X-Ray and Physiotherapy Equipment Kelley-Kcet's latest device—the Orthodiagraphoscope—will be shown, and also their compact system of units Bring your problems to us for our suggestions and advice and remember we have nineteen years of experience to guide us Our Mr Hamby of Rochester Office also Mr Wiberley of Troy, will be there to greet you

Booth 36—The McIntosh Electrical Corporation of Chicago, with forty-six years accumulated experience in the manufacture of Electro-Physiotherapy equipment, will have on display its latest models of apparatus, including the Biolite, the new Infra Red Ray Generator

Constant attention to the newer developments in apparatus and equipment in American and European clinics enable them to place at the disposal of the medical profession the latest products in modern Electro-Physiotherapy Equipment

Booth 2—James Picker, Inc., will exhibit some of the latest developments in the construction of X-Ray Equipment including the new

Table where the Bucky Diaphragm is built in and made an integral part of the Radiographic Table

On display also are the Six-Sixty Generator—the most powerful X-Ray Machine of its size available today, and a Vertical Fluoroscope, which will be found surprisingly easy of movement

The Polytherm Generator—a heavy duty diathermy machine—will also be on display and in actual operation

Booth 59—S Pongho & Co. will show a combination electric-heated treatment table that is used in combination with the vertical electric light bath Both products are of the highest standard from the point of application, construction and finish The table proper is finished in mahogany, with hair-filled cushions on top The interior of the electric bath cabinet is finished with highly polished German silver covered with five-ply asbestos, and then finished with the brown duck canvass

Descriptive literature will be distributed

Booth 24—The Sanborn Company will demonstrate metabolism testing and will feature the Sanborn Graphic, a simplified, compact oxygen consumption apparatus, and also the Sanborn Benedict—1926 Model This new model has as an integral part a firmly built, noiseless Kymograf which gives the story of the metabolism test in writing, and a quiet-running, dependable motor and blower—(slow speed) for circulation of air and comfort in breathing

Heart specialists are especially invited to see the Sanborn Electrocardiograf in operation This apparatus is constructed on the standard principle of the Einthoven Galvanometer, but is simplified for practical use in office or hospital

Booth 13—J Sklar Manufacturing Co.—The Imperator Treatment and Diagnostic Unit is the latest development in the line of Suction and Pressure Apparatus This new four-cylinder outfit will be featured at the booth This apparatus in reality is two machines in one, thereby

providing a powerful and efficient unit for simultaneous or separate use of suction or pressure without inter-communication. This progressive unit is incased in a beautifully designed cabinet, in which are built all the necessary aids to diagnosis and treatment in nose, throat and ear work.

Other late developments on display will be Stein-O-Lite and Dr. Harry Koster's Blood Transfusion Apparatus.

Booth 8—The Standard X-Ray Sales Corporation will exhibit X-Ray and Diathermy Apparatus manufactured respectively by the Standard X-ray Company of Chicago and the Lugenli Electric Company of Cleveland.

Inspect our new surgical combined Diathermy Apparatus and the DeLuxe Model one hundred twenty-five P K V combined X-ray, Fluoroscopic and Superficial Therapy Machine.

We will cheerfully demonstrate apparatus to the profession without any obligation whatsoever. If you have any Physio Therapy or X-ray installation problems, consult us as our fifteen years experience specializing in this field makes it possible for us to give you suggestions and layouts that are practical from the point of view of both patients and operators.

Booth 45—The Victor X-Ray Corporation will show a number of new pieces of equipment of interest to the roentgenologist and the physical therapist, as developed by the Research and

Engineering Departments of this organization.

The Motor-Drive X-ray Table, Stabilized X-ray Timer (especially adapted for "flash" radiography), Vertical Stereo-Radiographic Unit with Automatic Tube Shift and Rotating Bucky Fluoroscopic Grid are some of the major X-ray items that will be shown.

Take note of the Victor line of Diathermy apparatus (both medical and surgical), also the distinctive features in Victor Ultra-Violet Quartz 1 amp, the Wantz Multiple Wave Generator for galvanic and sinusoidal therapy, and Victor Phototherapy Lamps.

Booth 1—The Wappler Electric Company will display the Squier Cystoscopic X-Ray Table, Wyeth Endotherm, Clark Excell Diathermy apparatus and the new prismatic Stereoscope. Also a complete line of the A C M I Cystoscopes and Diagnostic Instruments including the new Dr. J. F. McCarthy Pan-Endoscope and the new Coralite Diathermy Accessories.

The Squier Cystoscopic X-Ray Table is finished in a highly polished hospital gray with nickel trimmings and polished black top and contains every necessary attachment and adjustment for convenient operation both as a cystoscopic examining table and a radiographic table.

The Endotherm, a surgical machine, will be also demonstrated.

FOODS

Booth 11—H. T. Dewey & Sons Company will exhibit and dispense samples of wine-grape juice, in order that physicians may test for themselves the deliciousness and nutritive value of the product.

Dewey's Wine-Grape Juice can be retained by the most delicate stomach when most other nourishment cannot be taken. It also has filled a long felt need for all post-operative cases and typhoid fever patients.

The limited quantity of fine sun-ripened south Jersey wine grapes from which Dewey's Wine-Grape Juice is made, make it impracticable to place it in the hands of all dealers. If you leave the name of your druggist at our booth we will arrange with him to carry a sufficient quantity to supply the needs of your patients and yourself.

Booth 46—The Dryco Milk Company, 15 Park Row, New York, will exhibit at its booth, No. 46 its product Dryco, a special milk for babies, and Protolac, a calcium caseinate. It will also have a souvenir for its medical friends. It will also give some handsome posters, printed in colors of the "Dryco Baby." These will be mailed to the doctor's homes upon request. Literature giving full data regarding the use of Dryco will be distributed.

Booth 32—The Horlick's Malted Milk Corporation, of Racine, Wisconsin, invites your attention to its exhibit at Booth 32 of Horlick's

the Original Malted Milk, a nourishing food drink in all wasting diseases, and easily digested and strengthening for convalescents. Including the vitamins and mineral elements both of the grain and of rich, full-cream milk, it is especially useful for expectant and nursing mothers, and in difficult infant feeding cases.

Booth 15—The Merrell-Soule Company will exhibit its group of dehydrated milk adaptations, Klim, Powdered Protein Milk, Powdered Lactacid Whole Milk and its new carbohydrate, Vi Mal-Dex. Representatives will be at the exhibit at all times prepared to discuss the merits of these preparations with visiting physicians.

Ice cold reliquified Klim and Klim Wafers will be served at the exhibit and souvenir boxes of the Wafers will be given to all physicians and physicians' wives desiring them.

Booths 41-42—The E. L. Patch Co., of Boston, Mass., will explain the manufacture and testing of Patch's Flavored Cod Liver Oil. There will be an interesting exhibit showing the various steps in the process of making cod liver oil from fresh livers. Some of the laboratory animals will be there too. These little albino rats play an important part in biological assay of Patch's Cod Liver Oil.

Booth 57—The Sanka Coffee Corporation will demonstrate a coffee from which at least 97 per cent of the Caffein has been removed, with-

out affecting the flavor or aroma and will show the various stages through which the coffee passes during the extraction process

Professor Dr M Mendelsohn, a specialist in the diseases of the heart, has written a very interesting article concerning the contra indications of caffeine, which will be distributed

Booth 6—The Abbott Laboratories will display a line of pharmaceutical preparations which

have been passed by the Council of the American Medical Association

Hear the story of Neonol, Neocinchophen, Butesin Picrate Ointment and Butyn

Take note of Metaphen, the non-staining, non-corrosive, organic mercurial, with marked bactericidal properties along with Arsphenamine, Neosarsphenamine, Sulpharsphenamine and Potassium Bismuth Tartrate

PHARMACEUTICALS

Booth 30—The Hoffman-LaRoche Chemical Works will exhibit well known remedies such as Digalen, Pantopon and Thiocol Syrup "Roche," and will in all probability feature a new and very useful "Roche" specialty at this meeting. The company's decision to have a booth at the 1926 and subsequent meetings has been reached, as they write in a recent letter, through the recognition of the constantly increasing importance of the annual meetings of the New York State Medical Society

A group of men from the staff of the Scientific Department will be in attendance and will explain the action of the products

Booth 25—Hynson, Westcott & Dunning will feature mercurochrome. Comprehensive information in regard to this germicide will be available, as will data on the other pharmaceutical specialties of this firm and on their diagnostic apparatus and agents

Booth 44—The Laboratory Products Company will exhibit its products, including S M A which is made by permission of the Babers and Children's Hospital of Cleveland where it was developed. It contains S M A fat which is like breast milk fat and it also has a low content of low volatile fatty acids. It also contains cod liver oil to make it anti-rachitic and anti-spasmodic

Booth 35—H. A Metz Laboratories, Inc., will display the Metz line of dependable original products

The feature of the display will be the assemblage of the latest information relative to these products and concerning their use, technique of preparation and administration, etc. Those in attendance will be glad of the opportunity to disseminate this information and to discuss any particulars pertinent thereto

Surgeons will be interested in the specially prepared sterile Novocain Crystals in hermetically sealed ampules for spinal anesthesia and other forms of Novocain and Novocain-Suprarenin, meeting their every need

Salvarsan Neosalvarsan, Silver-Salvarsan, Sulpharsphenamine, Anesthesin, Novocain, Albargin, Orthoform, Pyramidon and Suprarenin will be among the products exhibited

Booth 37—The Mutual Pharmacal Company, Inc., Syracuse, N. Y., will exhibit some of the products of its laboratory. It manufactures a general line of pharmaceuticals for physicians use. A complete and up-to-date analytical department is maintained to assay and standardize the products of the manufacturing departments

SUPPLIES FOR PHYSICIANS AND HOSPITALS

Booth 19—The Allison line of furniture represents more than a generation of designing and manufacture. The tendency of modern times in all departments of life is to eliminate as far as possible everything ugly, suggestive and unharmonious. As a meeting place for the sick and afflicted the physician's office should be cheerful and attractive. Suggestion whether consciously or unconsciously employed has a potent influence in securing for the practitioner that confidence from patient so necessary to the maintenance and upbuilding of a successful practice. The office equipped with Allison furniture suggests confidence and efficiency to the patient

Booth 16—The Anglo-French Drug Company of New York is the manufacturer and sole distributor of the Labat Outfit for producing

local anesthesia in accordance with Dr Labat's book on Regional Anesthesia

The Outfit for general surgery consists of six various size needles, one 10c bayonet lock syringe, one 2cc glass syringe, sterilizing tray and case. The outfit for eye, ear, nose and throat surgery has various attachments for doing surgery of the head and face (eye, ear, nose, throat, plastic, dental and oral surgery). It is also supplied with a sterilizing tray and case. These two outfits can be seen at our exhibit space

Booths 20-21—Becton, Dickinson & Company will show its lines of diagnostic and therapeutic apparatus, including the Luer B-D Syringes, Yale Quality Needles, Thermometers, Asepto Syringes, Ace Bandages, Leather Goods, Sphygmomanometers, Spirometers and

Stethoscopes The company has developed certain new items which are of interest to the profession in general and will demonstrate them in the booths

Booth 62—Frank S. Betz Company will exhibit its well-known line of medical and surgical supplies and office equipment. The company invites the doctors to call at its New York branch, at 6 West 48th Street, where a complete stock of supplies is carried. Orders will be delivered free in the Metropolitan district.

Booth 7—The Cambridge Instrument Company will exhibit two models of the Hindle Electrocardiograph, now widely used for clinical diagnosis of heart cases.

The Number Two Model, which is generally used in hospitals and medical colleges, will be exhibited as well as the Number Three Model, a compact equipment, designed for use of private practitioners.

The physicians of New York State have played a prominent part in the practical development of electro-cardiography, and there are at the present time 95 instruments in use in New York State alone about one-fifth of the total number installed in the entire country.

The exhibit will also include the McKenzie-Lewis Polygraph, Alveolar Air Indicator, Microtomes and other Cambridge Physiological Instruments.

Booth 64—The C. P. Chemical & Drug Company, of 114 Liberty Street, New York, N. Y., have an exhibit of the Landecker-Steinberg Non-Burning Ultra Sun Lamp. It is a carbon arc lamp utilizing electrodes specially impregnated so as to emit a continuous spectrum of ultra violet rays between 2,900 and 4,000 angstrom units. These rays are the biologically constructive rays identical with the natural noon-day sunlight obtained at high altitudes. Practically no destructive or short-wave rays are emitted. The lamp requires no cooling equipment and is mechanically foolproof. It is mobile and is equipped with a globular, highly polished nickel reflector, which concentrates the beneficial rays emitted and reflects them in such a manner as to obtain the maximum efficiency.

Booth 50—DeVilbiss Sprays, for office use and prescription purposes will be on display in Space No. 50 at the Annual Meeting in New York.

Booth 40—The Foregger Company, Inc., manufacturers of the Gwathmey Anesthesia Apparatus, will exhibit its Universal Metric Gas Machine.

This machine, made in three different models, accurately measures the flow of seven different gases, Nitrous Oxide, Ethylene, Propylene, Nitrogen, Acetylene (Narcylene), Oxygen and Carbon Dioxide.

The flow meters of the Metric Gas Machine are water gauges, calibrated for above gases, according to requirement, in c.c.s. per minute or liters per minute.

Research workers, who have been unable to compare results on account of the inaccuracy of "percentage indicators" will appreciate the advantages offered in this new Metric Gas Machine.

Booths 17-39—The Harold Surgical Corporation is again exhibiting to its friends of the New York State Medical Society, its line of surgical supplies, instruments, furniture, electrical therapeutic apparatus, sterilizers and other items of medical equipment.

The Harold Surgical Corporation is sensitive to the ever-increasing demands for new therapeutic aids made by the profession, and is meeting these demands as quickly as possible with only the highest grade products from the best known sources.

The Harold Surgical Corporation has rearranged its organization so that 24 hour service is now being given. The company is aiming to enable the doctor to secure all of his merchandise from a single source, and to get the highest grade of instruments and supplies in the shortest possible space of time.

The company extends a hearty welcome to all its friends and it includes amongst its friends all the members of the New York State Medical Society.

The exhibit will include all the supplies that are listed in their catalogue, together with a number of recent additions which have not yet been listed.

Booth 10—The Hanovia Chemical & Mfg. Co., of Newark, New Jersey, will exhibit its standard Quartz Lamps, the *Alpine Sun Kromayer* and *Luvor*, together with the radiant heat lamp, the *Sollux*, both types, the Floor Stand and Desk model.

It will also exhibit a new Upright Portable Unit, which has a self-contained water system for the *Kromayer Lamp*, and also a Combination Unit, with the *Alpine Sun Lamp* attached, a highly practical instrument, having a very wide scope of operation.

Booth 71—Hospital Supply Company and The Watters Laboratories are demonstrating three articles of particular interest to the orthopaedic surgeons. They are giving a practical demonstration of Dr. Moorhead's new Electric Bone Operating Set which presents extremely novel features. A new Plaster Paris Bandage Roller by Dr. Edgar Oppenheimer is being exhibited for the first time. They are also showing a reasonably priced, very efficient and compact modern sterilizing outfit for doctors' offices. Their new Orthopaedic and Fracture Table eliminates many disadvantages of previous tables and includes some additional features. They are

also showing a complete line of Stainless Steel Surgical Instruments

Booth 9—E. B. Meyrowitz Surgical Instrument Co., Inc., will show the new Meyrowitz Trial Frame, Giant Ophthalmoscope and Retinoscope, Morton Perimeter, set of Bell's Eye Specula and new Jamisons Advancement Forceps. There will also be on display the Alexander Ear Syringe, Hajek-Kofler Sphenoid Punch, Hasslinger's Directoscope and Callahans Haemostat.

Of interest to the general practitioner will be the Wolf Mouth Gag, Braun's Snaretome, Sonderman Suction Outfit and Berger Loupe.

A special attraction will be the Wellsworth Ophthalmic Chair Unit and Imperatori Outfit.

Booth 3—V. Mueller & Co will exhibit its specialties in the instrument line, including the Lancaster Eye Magnet, the Shahan Ophthalmic Operating Light, Mastoid, Autrum and Sinus instruments, and the Kelley Direct Vision Adenotome. The exhibit will be in charge of Henry G. Herold, eastern agent.

Booth 70—Multiplex Display Fixture Company, New York, (Gen Off.) St Louis, Chicago, exhibits a Lantern Slide Cabinet giving slides protection from dust, damage and theft, and at the same time keeping the slides conveniently accessible.

The cabinets are equipped with all-steel slide racks, or frames, which hold the slides in vertical position. Each slide rack holds 56 slides, which are securely held in place between metal channels, yet any slide may be instantly lifted out of the frame and as readily replaced.

It also manufactures a large line of swinging fixtures for display and visualization of printed matter charts, etc. These fixtures used for classroom, lecture work, exhibit and convention displays.

Booth 31—Pfeau's American Instrument Co., New York, will exhibit a full line of new anatomical specimens and teaching material, as well as the latest, ear, nose and throat instruments and specialties for plastic surgery and nasal correction. Special features are Set of specimens showing Dr Halle's various sinus operations,

Lined nose specimen especially prepared for teaching and demonstrating,

Seibert's latest Directoscope,

Joseph's nasoplastic instruments,

Maltz' new Rhinoplastic instrument set,

Brandenburg's instruments for bloodless nasal correction, etc.

Booth 34—The Prometheus Electric Corporation will demonstrate its new line of low-priced autoclaves which are attracting attention because of their efficiency and rapid operation. Cabinet models will be displayed showing this pressure sterilizer in combination with various water and instrument sterilizers.

Booths 28-29—C. M. Sorensen Co., Inc., Long Island City, New York.

The principal feature of this exhibit is the Company's new equipment for nose and throat work, called the "De Luxe." It consists of an eight-drawer steel cabinet, with compartment containing separate pumps for pressure and for suction, each pump having its own electric motor. A variety of pressure appliances are grouped at one side of the cabinet, the suction appliances at the other, supplies and medicines in jars and bottles, also a waste receptacle. Pressure and suction each has its own panel, containing complete controls. The center panel carries controls for the transilluminator, diagnostic lamp, and cautery.

Booth 63—The Spencer Lens Company will exhibit a complete line of precision optical instruments of interest to the Medical Profession.

Among other things there will be shown the latest developments in a Research Mon-Objective Binocular Microscope, the standard Laboratory Microscopes, New Universal Low Power Binocular Microscope, Portable Microscopes, complete equipment for dark field work with the microscope, Clinical Microtome, Colorimeter, and a new method of stereopticon projection using standard motion picture film in place of lantern slides.

The Spencer Lens Company representatives will be pleased to demonstrate or explain any instruments in which you have an interest.

Booth 14—George Tiemann & Co will show late model instruments including the Barton and Bailey-Williamson Obstetric forceps, the Lilienthal Rib Guillotine, the Unger Transfusion apparatus and the Pfarre two-way syringe, also various patterns of instruments made of rustless steel. It will include diagnostic instruments and various appliances used in treatment of syphilis. Such items as may not be available at our Booth can be quickly obtained from our store.

The Post Electric Cautery will be on display at our Booth No 14. It embodies the following features: used on either alternating or direct current without rheostat or transformer, solid silver tips of assorted patterns, produces uniform correct temperature, is light and portable but sturdy in construction, tips designed for uterine, hemorrhoid, sarcoma and nose and throat conditions.

Booth 27—Carl Zeiss, Jena, U. S. Agency, is exhibiting an assortment of its celebrated, high-grade optical instruments including Monocular and Binocular Microscopes of latest design Photomicro Camera Phoku, Gullstrand Ophthalmoscope and Refractometer, Demonstration or Poly-Laryngoscope, Dipping Refractometer for serum work, Hand Spectroscopes, Cystoscopes and Electro-Medical Instruments, Hess Operating Lamp, Magnifiers, etc.

Competent demonstrations of any instrument shown will be gladly given by those in attendance.

Stethoscopes The company has developed certain new items which are of interest to the profession in general and will demonstrate them in the booths

Booth 62—Frank S. Betz Company will exhibit its well-known line of medical and surgical supplies and office equipment. The company invites the doctors to call at its New York branch, at 6 West 48th Street, where a complete stock of supplies is carried. Orders will be delivered free in the Metropolitan district.

Booth 7—The Cambridge Instrument Company will exhibit two models of the Hindle Electrocardiograph, now widely used for clinical diagnosis of heart cases.

The Number Two Model, which is generally used in hospitals and medical colleges, will be exhibited as well as the Number Three Model, a compact equipment, designed for use of private practitioners.

The physicians of New York State have played a prominent part in the practical development of electro-cardiography, and there are at the present time 95 instruments in use in New York State alone about one-fifth of the total number installed in the entire country.

The exhibit will also include the McKenzie-Lewis Polygraph, Alveolar Air Indicator, Michromotes and other Cambridge Physiological Instruments.

Booth 64—The C. P. Chemical & Drug Company, of 114 Liberty Street, New York, N. Y., have an exhibit of the Landecker-Steinberg Non-Burning Ultra Sun Lamp. It is a carbon arc lamp utilizing electrodes specially impregnated so as to emit a continuous spectrum of ultra violet rays between 2,900 and 4,000 angstrom units. These rays are the biologically constructive rays identical with the natural noon-day sunlight obtained at high altitudes. Practically no destructive or short-wave rays are emitted. The lamp requires no cooling equipment and is mechanically foolproof. It is mobile and is equipped with a globular, highly polished nickel reflector, which concentrates the beneficial rays emitted and reflects them in such a manner as to obtain the maximum efficiency.

Booth 50—DeVilbiss Sprays, for office use and prescription purposes will be on display in Space No. 50 at the Annual Meeting in New York.

Booth 40—The Foregger Company, Inc., manufacturers of the Gwathmey Anesthesia Apparatus, will exhibit its Universal Metric Gas Machine.

This machine, made in three different models, accurately measures the flow of seven different gases, Nitrous Oxide, Ethylene, Propylene, Nitrogen, Acetylene (Narcylene), Oxygen and Carbon Dioxide.

The flow meters of the Metric Gas Machine are water gauges, calibrated for above gases, according to requirement, in c.c.s. per minute or liters per minute.

Research workers, who have been unable to compare results on account of the inaccuracy of "percentage indicators" will appreciate the advantages offered in this new Metric Gas Machine.

Booths 17-39—The Harold Surgical Corporation is again exhibiting to its friends of the New York State Medical Society, its line of surgical supplies, instruments, furniture, electrical therapeutic apparatus, sterilizers and other items of medical equipment.

The Harold Surgical Corporation is sensitive to the ever-increasing demands for new therapeutic aids made by the profession, and is meeting these demands as quickly as possible with only the highest grade products from the best known sources.

The Harold Surgical Corporation has rearranged its organization so that 24 hour service is now being given. The company is aiming to enable the doctor to secure all of his merchandise from a single source, and to get the highest grade of instruments and supplies in the shortest possible space of time.

The company extends a hearty welcome to all its friends and it includes amongst its friends all the members of the New York State Medical Society.

The exhibit will include all the supplies that are listed in their catalogue, together with a number of recent additions which have not yet been listed.

Booth 10—The Hanovia Chemical & Mfg Co., of Newark, New Jersey, will exhibit its standard Quartz Lamps, the *Alpine Sun Kromayer* and *Luvor*, together with the radiant heat lamp, the *Sollux*, both types, the Floor Stand and Desk model.

It will also exhibit a new Upright Portable Unit, which has a self-contained water system for the *Kromayer Lamp*, and also a Combination Unit, with the *Alpine Sun Lamp* attached, a highly practical instrument, having a very wide scope of operation.

Booth 71—Hospital Supply Company and The Watters Laboratories are demonstrating three articles of particular interest to the orthopaedic surgeons. They are giving a practical demonstration of Dr. Moorhead's new Electric Bone Operating Set which presents extremely novel features. Agency, is exhibiting an assortment of its celebrated, high-grade optical instruments including Monocular and Binocular Microscopes of latest design Photomicro Camera Phoku, Gullstrand Ophthalmoscope and Refractionometer, Demonstration or Poly-Laryngoscope, Dipping Refractometer for serum work, Hand Spectroscopes, Cystoscopes and Electro-Medical Instruments, Hess Operating Lamp, Magnifiers, etc.

Competent demonstrations of any instrument shown will be gladly given by those in attendance.

NEWS NOTES

THE SARATOGA SPRINGS STATE PARK

Editor, New York State Journal of Medicine

The Saratoga Springs Medical Society is taking an active interest in the development of the mineral springs in the State Park in order to make them available for popular use, both internally and externally. Believing that physicians generally are not well informed regarding the Springs and the plans for their development, I am instructed by the members of the Medical Society to request you to publish this letter of information.

Far back in the early ages of geologic time, a cataclysm occurred in the Saratoga rocks which produced a crack or fault running northeast and southwest. The rocks on the westerly side of the fault were displaced upward for a vertical distance of approximately two hundred and fifty feet, and a rift, hundreds of feet in depth, was left up which the underground waters bubble as from an artesian well. As the water flows through the limestone strata, which is the predominating rock formation, they dissolve the lime, soda, iron, sulphur and other minerals and become charged with carbon dioxide and other gases and finally appear on the surface as mineral springs. Borings have revealed mineral waters at a depth of over seven hundred feet.

The value of the Saratoga mineral waters was first made known to the white race by the Indians in 1767 and from that time on to the end of the 19th century the waters of Saratoga enjoyed an ever increasing popularity with the people seeking health. The reputation of the mineral waters became world-wide and Saratoga reached the height of its popularity as a health and fashion resort about the middle of the 19th century. People from all over the United States and some foreign countries came to Saratoga to drink the health-giving waters and enjoy the rest afforded by the pleasant surroundings. But little or no attention was paid to the use of the waters for bathing purposes, no attempt having been made save in a very crude way to develop this part of the cure system.

Immediately following the year 1900, the private exploitation of the highly carbonated mineral waters for their carbonic acid gas, and wasting the mineral waters were continued. In 1909, a law was passed by the Legislature of the State of New York creating the Reservation at Saratoga Springs and a commission to administer it.

During their tenure of office the Commissioners appropriated for the State over 150 mineral springs and wells and about 350 acres of land. They divided the land purchased into three dis-

tinctive parks—High Rock, Lincoln and Geyser—and with the means at their command laid out a general scheme of park development. The Commission caused to be made by its engineers and chemists a thorough investigation of the various mineral springs acquired, and assembled a great mass of valuable data pertaining to the mineral water area throughout the Saratoga quadrangle. Lack of appropriations prevented the Commissioners from carrying into effect many of the plans they had in mind for the development of the Reservation properties.

In 1916, the State decided to adopt a new policy and turned the State Reservation at Saratoga Springs over to the Conservation Commission, which proceeded to execute this plan with all possible dispatch. This plan embodied the development of the several parks and providing attractive walks and drives on the Reservation. Well designed structures were provided at the more important springs where people could obtain the mineral waters at the fountain head in a natural state.

The Commission also turned its attention to the development and use of the waters for bathing purposes. It realized that no health resort, based upon the use of mineral waters, could be complete which did not provide for the administration of the mineral waters externally as well as internally. The bath houses on the Reservation, three in number, were found to be unsuitable for scientific work and after investigation and considerable research work, the Commission made a complete rearrangement of its bath establishments. Today, the State in its Lincoln Park has two modern bath houses, with the most complete equipment for the administration of carbonated mineral baths and the giving of other forms of hydrotherapeutic treatments.

The Lincoln Bath House contains 147 solid porcelain tubs, adequate dressing and rest rooms, and a well equipped hydrotherapy treatment. It is particularly well arranged to serve the great number of people of moderate means who patronize it during the cure season.

The Washington Bath House is designed for a somewhat higher class of patronage. It provides for the convenience and comfort of its patrons and for the administration of the treatments in a most scientific manner. The dressing room facilities are ample and the quiet rest rooms are divided into alcoves which contain two or three couches, so that the maximum of privacy is secured. At the end of each of these wings is a section given over to private suites.

comprising a bath room, dressing room and rest room, where those desiring it may obtain absolute privacy during their treatment and rest period.

In both the Lincoln and Washington Bath Houses the latest forms of hydrotherapeutic treatment may be obtained. Here are given electric cabinets, neurovascular or eliminating treatments, packs, douches, formentations, and colon irrigations, as well as all forms of massage. However, the one point in which the State's bath houses differ from any others on the American continent is in the giving of the mineral baths with naturally carbonated and naturally mineralized waters. The waters of the Lincoln tract are used in the bath houses for this purpose and are collected and stored by means of a specially designed and constructed system so that the supply of water for the baths shall at all times be ample and be highly carbonated with its own gas. This water is conveyed to the porcelain tubs in the bath houses and there heated to the proper temperature. The temperature and gas content of the bath as administered is closely controlled and carefully regulated by a skilled attendant so that the patient and his physician may be assured that the treatment is given as prescribed.

All of these facilities are set in the midst of six acres of well kept lawns, dotted with shrubbery and intersected by paths and drives for the convenience and pleasure of the patrons, and the whole tract is backed by a luxurious growth of pines and other evergreen trees, making in all a delightfully pleasant place in which to recover one's health and vigor.

To serve the small number of patients who apply for treatment during the winter months, a small and compact bath house has been installed in one of the State owned buildings in the City of Saratoga Springs. This department is a miniature of the larger bath houses just described. Here can be obtained the genuine carbonated mineral water baths with the same water as is used during the summer months at the Lincoln and Washington Bath Houses. Here, also, are electric light cabinets, colonic apparatus, and all necessary equipment to give every form of hydrotherapeutic treatment. A mechanotherapy department has also been installed in this bath house in charge of a competent attendant.

The combined capacity of the bath houses operated by the State at Saratoga Springs equals 2,200 treatments per day, and with the additions which are anticipated during the coming year this maximum capacity will be increased to approximately 4,000 treatments daily.

With the completion of the work in Lincoln Park, the State will have complete the first step as outlined in its plan for the development of

the Reservation. The Commission thought that the great mass of people of moderate means should be the first care of the State and to that end has devoted its efforts up to the present time.

The next step in the State's plan will be the development on its property in the City of a modern well equipped bath house combined with a drink hall or Kur-haus, and the parking of the property surrounding it. This development will serve a class of people entirely distinct from that which now patronize the Washington and Lincoln Baths. The style of architecture will be more elaborate and the interior appointments and equipment for the administration of the treatments and for caring for the patients more luxurious. The bath establishment will be so arranged that it will serve winter as well as summer patients, and will contain the administrative offices of the Division.

It is expected that complete plans, specifications and estimates will be made for this development this year and the money appropriated for the carrying on of the work in 1927. During the year 1927 plans will be made for the next and *last step* in the development, which will be the erection of a combined hotel and sanitarium directly connected to a magnificent bath house, located in Geyser Park on the plateau overlooking the Vale of Springs.

Geyser Park will be landscaped and provisions made for all forms of winter sports—skiing, snow shoeing, tobogganing and skating. Funds to carry on these last two steps of the program are to come from the 100 million dollar bond issue recently approved by the people, and should be made available to start this work in the year 1928 which, when completed, will bring to its conclusion the development of the State's health resort at Saratoga Springs.

When the plans are carried out as outlined, the combined facilities of the three steps of the development—Lincoln, Saratoga City and Geyser—will enable the State to take care of from five to six thousand patients daily and make Saratoga Springs the largest cure center in the United States and the equal of any in Europe.

The local Medical Society already has a Committee that is acting in an advisory capacity to the State authorities who have charge of the Park. The local physicians are deeply interested in the development of the Springs and it is their hope and expectation to see them developed in a manner that is both scientific and ethical.

(Signed) E. H. KING,
President, Medical Society
of the County of Saratoga,

CARL R. COMSTOCK,
President Medical Society of Saratoga Springs

WOMEN'S MEDICAL SOCIETY OF NEW YORK STATE, INC

The annual meeting of the Women's Medical Society of New York State, Inc, will be held on Monday, March 29, in the Hotel McAlpin, 34th Street and Sixth Avenue, New York

It is the custom of this society to meet during the sessions of the Medical Society of the State of New York, and there is a spirit of friendly cooperation between the two organizations and their memberships overlap

The society will hold a session in the morning, and the members will be guests of the Women's Medical Association of New York City in a sightseeing tour to medical centers in the early afternoon

A reception will be given in the Hotel McAlpin at 4 P M by Dr Rosalie S Morton, and a banquet will be held in the evening, with Dr Elizabeth B Thelberg as toast-mistress

Tickets for the banquet, \$4 00, may be obtained from Dr Harriet F Coffin, 426 East 26th St, New York City

Program of the morning session is as follows

Hotel McAlpin, 9 30 A M

Invocation, Eliza M Mosher, M D

Report of Secretary, Anna Harvey Voorhis, M D

Report of Treasurer, Harriet F Coffin, M D

Reports of Committees Scientific Program, Marie L Chard, M D, Chairman, Legislation, Florence A Sherman, M D, Public Health,

Josephine Bicknell Neal, M D, Medical Education, Mary T Greene, M D, Arrangements, Mary Dunning Rose, M D, Arrangements Women's Medical Association of New York City, Frances Cohen, M D

SCIENTIFIC PROGRAM

Immunization against Diphtheria and Scarlet Fever, Mary J Kazmierczak, M D Discussion opened by Louise M Beamis, M D, and May Salona Holmes, M D (by invitation)

The Technique and Effect of Radium Treatment on Cancer of the Cervix (lantern slides), Lillian K P Farrar, M D Discussion opened by Elsie S L'Esperance, M D, and Leila C Knox, M D (by invitation)

Cysts of the Breast (lantern slides), Elsie S L'Esperance, M D Discussion opened by Lillian K P Farrar, M D

Diabetes, Its Types and Treatment, Agnes Brown, M D Discussion opened by Emily Levi, M D

Basal Metabolism, Its Determination and Clinical Value, Connie Guion, M D Discussion opened by Margaret E Fries, M D

Management of Transverse Presentation, Georgia Reid, M D Discussion opened by Caroline Finley, M D

Election of Officers
Luncheon

TRI-STATE CONFERENCE

The Second Conference of the representatives of the Medical Societies of New York, New Jersey and Pennsylvania was held on the afternoon of February 26th, in the New York Academy of Medicine. The presidents, secretaries and editors of the three societies were present, and the total attendance was fourteen. Dr Van Etten, President of the New York State Society, presided and led a symposium on the leading topics which were under consideration by his society. The discussion developed the fact that the same problems confronted the medical societies in the three states, and that they had been solved with varying degrees of success. While each state excelled the others in certain activities, no one led the rest in all. While New York, for example, had an excellent record in graduate education, the other two states excelled in medical defense.

The group assembled was so small that the discussions could be largely informal, and the participants were so well versed in the affairs of their own societies that they were ready with their data and could show that their opinions were based on facts.

Graduate education was the first topic to be dis-

cussed. Dr C A Gordon, Chairman of the Committee on Public Health and Medical Education, told how New York had developed a series of lectures and demonstrations on common, practical topics, especially in pediatrics and obstetrics, in cooperation with the State Department of Health. He had dealt directly with the county medical societies who had permitted all their members to attend the lectures without charge. This Committee had also stimulated the county societies to put on practical programs at their regular meetings, and to hold extra meetings to carry out programs on the art of practicing medicine.

The representatives of Pennsylvania reported activities in graduate education along totally different lines. Their Society had worked with the medical schools who had detailed teachers to go to central hospitals and hold series of clinics and demonstrations for the benefit of doctors who would enroll for the courses and pay the fees which were required. New Jersey followed Pennsylvania's plan.

The relation of the State Medical Society to the use of toxin-antitoxin for diphtheria prevention was the second topic that was discussed.

The health forces of New York State were combined in a campaign to secure its application to all children. Dr. Gordon outlined a plan by which the county medical societies should take up the question and develop a plan for educating their members to give the immunizations in their private practices. Dr. Alec N. Thomson, Secretary of the Public Health Committee of the Medical Society of the County of Kings, described his recent visit to Buffalo where the Erie County Society devoted an evening to devising means by which the Society could promote the immunizations, especially in stimulating physicians to give them in their private practices.

In Pennsylvania the most widespread use of toxin-antitoxin had been in those counties which had a full-time health officer.

Periodic Health Examinations was the third topic to be discussed. The reports from New York State were that the method of making the examinations had been perfected and systematized, and the next step is that the county societies shall stimulate their members to make the examinations.

The Medical Society of the State of Pennsylvania had adopted the plan of Kings County and had made examinations of the doctors at the meeting, as a demonstration of the methods. A

large proportion of the doctors examined were found to have serious defects. The County Medical Society of Philadelphia has set aside a room of its new home for demonstrations of periodic examinations, and will stress them during the National Exhibition this Summer.

Defense in Malpractice Suits was the fourth and last topic to be discussed. New Jersey has group insurance and indemnity for \$16 per \$10,000 insurance while the same policy costs \$32 in New York. But New Jersey has only four suits per 1,000 doctors annually, while New York has four times as many.

Pennsylvania has no group insurance plan, but the State Society has a fund to supply counsel for the defense of the insured members. Yet the cost of the insurance was less than one dollar per member. Very few lay suits were brought against doctors because their colleagues were always ready to go to court in their defense. The conference voted unanimously in favor of the principle of defense in malpractice suits, but made no decision regarding the method of the defense.

Every moment of the conference was practical and full of interest. The next one will be held in Philadelphia at the call of the leaders of the Pennsylvania Society.

PLAN FOR CHILDREN'S CONSULTATION CLINICS

Adopted by the Medical Society of the County of Montgomery

Places—Hagaman (20), St. Johnsville (40), Ft. Plain (40), Canajoharie (40), Palatine Bridge (20), Fonda (20), Fultonville (20), Ft. Johnson (20), Minerva (20), Rural Grove (20), Nelliston (20), Tribes Hill (20), Ft. Hunter (20), Cranesville (20). Numbers indicate children probably available—20 per examiner per day.

Type of Clinic—No cases under care of a physician to be examined, except by request of the attending physician. Children from age of 6 months until entrance to school.

Examination—Follow plan indicated on standard blank furnished by Child Welfare Division.

Clinic Hours—10-12 a.m., 1:30-4:30 p.m.

Compensation of Examiners—To be paid from local health budget, aided by a contribution from Child Welfare Division.

Equipment Needed—Stethoscope, Oscope, small bath robes for children, sheets for tables, gowns for examiner, scale and measuring rod, screens, one room for dressing room, quiet room for examiner, heated building when indicated by season, tongue blades, paper towels, wash-basins, soap (bar and liquid).

Examiners—To be designated by P. H. Com-

mittee of the County Medical Society, and assignments to be made by this Committee or a sub-committee of the P. H. Committee. Preferably H. O. and School Medical Inspectors to be selected, if and when authorized to do so by resolution of the County Medical Society.

Nursing Service—P. H., School, and Industrial Nurses to be invited to participate, compensation of Nurses may be necessary in a few instances.

Patients—Children who are apparently and presumably well, for the discovery of remediable defects.

Pledge Cards—To be signed by the family physician. Preliminary distribution by a volunteer committee of local women (preferably those who own and drive cars) with a chairman. Collection of the cards by the same committee and occasional transportation of the children to and from the clinics. Attendance hour to be assigned to each case, both to keep examiner busy and prevent overcrowding.

Ethics—No medical advice to be given, except in rare cases where there is not and has not been a family physician, in which instances the local H. O. will sign the cards. These ex-

annuations are for the discovery of remediable defects, and to cultivate the habit of annual or semi-annual examinations, and in every instance the Mother is to be advised that the corrections are to be guided by her family physician

Reports—Report sent to family physician and copies to H O and P H Nurse

Follow-up Service—Ten days after each local Clinic, P H Nurse with her copy of report to interview each physician, and to visit the family only when requested to do so by him, and when such permission is given, to periodically visit the family and urge the corrections found to be needed. The whole purpose of the Clinics is to bring about remedial activities on the part of parents, and since the family physician manifestly cannot urge these activities personally, the necessity of follow-up work by nurse is self-evident

Follow-up Clinics—It will probably be expedient to have Tonsil Adenoid, Orthopaedic, and similar types of Clinics, as a result of these, and these can be arranged for at places in the County that will be convenient as to times and types

Adjunct to T-1 Campaign—Each examiner should urge every parent to have the children protected by Toxin-antitoxin, at every Clinic. Explain the simplicity, the effectiveness and the freedom from harm of the inoculations, and convince them that this is an ordinary office procedure by every physician *

* Note So far as possible avoid the use of the word "Schick" and use the word "Immunization"

N B—The Health Officers of the County with the District State Health Officer, constitute the Public Health Committee

BULLETIN ON SILICOSIS

A special medical bulletin on the subject of Silicosis, or the infiltration of the lungs with stone dust, has been issued by the New York State Department of Labor. Its introduction states

"Anticipating legislation in the near future with a view to affording compensation to workers in industry suffering from silicosis, this bulletin is submitted for the convenience of those physicians in New York who may be interested

"Silicosis has been the cause of a number of deaths among certain groups of industrial workers, and no doubt has been unrecognized and entered as fibroid phthisis, pulmonary tuberculosis and bronchitis

"In compiling this resume of the literature of silicosis the aim was to make only those references from medical literature in detail which are

likely to be of assistance to the general practitioner

"There seems to be ample evidence that as a result of a careful study of silicosis the number of cases to be so diagnosed will increase"

The bulletin consists of 68 pages, of which 20 contain a well-written description of the condition, its causes, pathology, symptomology and management. The remaining pages are filled with quotations from standard authors

The bulletin is of great value to physicians especially those who deal with tuberculosis and other conditions of the lungs. Any physician may obtain a free copy by addressing Director, Bureau of Industrial Hygiene, New York State Department of Labor, 124 East Twenty-eighth Street, New York City

DR AUGUSTUS WALTER SUITER

A MEMORIAL

Dr Augustus Walter Suiter who died in the Village of Herkimer on May 28, 1925, aged 75 years was above the ordinary both as a physician and a man. Born in Herkimer and living there all his life, he achieved a large degree of respect and fortune. His public spirit is attested by his record service of fifty-one and a half years as Secretary of the Herkimer County Medical Society. He was President of the Medical Society of the State of New York during the year 1891 and for eleven years he was a member of the State Board of Medical Examiners. He was a scholar, a research worker, especially in chemistry, versed in medico-legal lore a wide reader and a man of all round culture. As a business

man he was successful to such an extent that he was able to leave bequests of \$80,000 for public purposes among them \$6,000 to the Medical Society of the State of New York to establish a lectureship, \$6,000 to the New York Academy of Medicine and \$3,000 to the Medical Society of the County of Herkimer. He gave his commodious residence to the Historical Society of the County of Herkimer and directed that one room should be used by the County Medical Society as a permanent headquarters.

After a long and honorable career as a practitioner of medicine, his life service will continue through the years in ever broadening circles of influence.

MEDICAL PROGRAM

OFFICERS FOR 1925-1926

President—Nathan B Van Etten, New York.
Speaker—E. Eliot Harris, New York.
Vice-Speaker—George M Fisher, Utica
First Vice-President—William H. Ross Brentwood.
Second Vice-President—Frederick H. Flaherty, Syracuse.
Secretary—Daniel S Dougherty, New York
Assistant Secretary—Howard Gillespie Myers, New York
Treasurer—Charles Gordon Heyd New York.
Assistant Treasurer—James Pedersen New York

Councillors

First District—John A Card, Poughkeepsie.
Second District—Joseph S Thomas, Flushing
Third District—Charles P McCabe, Greenville.
Fourth District—Horace M Hicks Amsterdam.
Fifth District—Nelson O Brooks Oneida.
Sixth District—George H Fox, Binghamton.
Seventh District—William I Dean, Rochester
Eighth District—Harry R. Trick, Buffalo

Standing Committees

Committee on Public Health and Medical Education
Charles A Gordon, Chairman, Brooklyn, George F Chandler, Kingston E. MacD Stanton, Schenectady, William D Johnson Batavia, Frank D Jennings Brooklyn, Louis A Friedman New York, Herman G Weiskotten, Syracuse, Martin B Tinker, Ithaca, Robert S MacDonald, Plattsburg

Committee on Legislation

Henry L. K. Shaw Chairman Albany, Arthur W Booth Elmira, Clarence F Graham, Albany

Committee on Medical Economics

William W Britt Chairman, Tonawanda, Charles O Boswell Rochester, Henry B Doust, Syracuse, Arthur S Chittenden, Binghamton, Nelson K. Fromm, Albany

Committee on Scientific Work

Andrew MacFarlane Chairman Albany L. Whittington Gorham Albany Edward S Van Duyn, Syracuse Alfred C. Beck, Brooklyn Eugene E. Hinman Albany Roger H Dennett, New York, Clarence O Cheney, Utica, Arthur D Jaques Lynbrook, Samuel J Kopetzky New York.

Committee on Arrangements

Edward R Cuniffe Chairman New York, John E. Jennings, Brooklyn William P Healy New York, Edward W Weber White Plains Simon M Jacobs, New York, Samuel J. Kopetzky New York, Isidore H Goldberger New York Edward C. Podvin New York, Henry Roth New York

Section Officers

Medicine—Chairman, L. Whittington Gorham Albany
Secretary Wardner D Ayer, Syracuse.
Surgery—Chairman Edward S Van Duyn, Syracuse,
Secretary George E. Beilby, Albany
Obstetrics and Gynecology—Chairman, Alfred C. Beck Brooklyn, Secretary, Nathan P Sears, Syracuse.
Pediatrics—Chairman—Roger H. Dennett, New York,
Vice-Chairman, Arthur W Benson, Troy, Secretary, John Aikman Rochester
Eye, Ear Nose and Throat—Chairman, Eugene E. Hinman Albany, Secretary James W White New York

Public Health, Hygiene and Sanitation—Chairman Arthur D Jaques, Lynbrook, Secretary, Leo F Schiff, Plattsburg

Neurology and Psychiatry—Chairman, Clarence O Cheney Utica Secretary, Thomas K. Davis, New York

By-Laws

Section 85 No address or paper before the Society, except those of the President and orators, shall occupy more than twenty minutes in its delivery, and no member shall speak upon any question before the House of Delegates for longer than five minutes nor more than once on any subject, except by the consent of a majority vote.

Sec. 86 All papers read before the Society by its members, shall become the property of the Society. Permission may be given however, by the Council, House of Delegates or the Executive Committee, to publish such paper in advance of its appearance in the *NEW YORK STATE JOURNAL OF MEDICINE*.

Sec. 87 Any distinguished physician of a foreign country or a physician not a resident of this state, who is a member of his own state association, may become a guest during any annual session upon the invitation of the President or officers of the Society, and may be accorded the privilege of participating in all the scientific work of the session

The Medical Society of the State of New York

17 West 43rd Street, New York

March 8, 1926

The regular annual meeting of the Medical Society of the State of New York will be held on Wednesday, March 31 1926, at 8 P M, in the Ballroom of the Waldorf-Astoria, New York

NATHAN B VAN ETTEN, M D, *President*
DANIEL S DOUGHERTY, M D, *Secretary*

March 8, 1926

The regular annual meeting of the House of Delegates of the Medical Society of the State of New York, will be held on Monday, March 29, 1926 at 2 P M, in the Waldorf-Astoria, New York

E ELIOT HARRIS, M D, *Speaker*
DANIEL S DOUGHERTY, M D, *Secretary*

By-Laws

Section 67 Each member in attendance at the annual meeting, special or intermediate stated meetings of the Society, shall enter his name and the name of the component county medical society to which he belongs in a register to be kept by the Secretary of the Society for that purpose. No member shall take part in any of the proceedings of such a meeting until he shall have complied therewith

Sec. 68. All members in good standing so registered may attend and participate in the proceedings and discussions of the general meetings of the Society and of the sections

Sec. 69 The following shall be the order of business at all general meetings of the Society

- 1 Calling the Society to order
- 2 Address of Welcome by the Chairman of the Committee on Arrangements
- 3 Reading the minutes of the last meeting
- 4 President's address
- 5 Special addresses
- 6 Reading and discussion of papers
- 7 Miscellaneous business

Registration

The Bureau of Registration and Information will be located in the Waldorf-Astoria. Only those who have registered will be admitted to the Section Meetings and Meeting of the Society. All desiring information or assistance of any kind should apply to the Bureau.

The Bureau will be open on Tuesday, Wednesday and Thursday

120th ANNUAL MEETING

Ballroom, Waldorf Astoria

Wednesday, March 31st, 8 P M

Calling the Society to order by the President, Nathan B Van Etten, M D

Address of Welcome by the Chairman of the Committee on Arrangements, Edward R Cuniffe, M D

Reading of the minutes of the 119th Annual Meeting by the Secretary, Daniel S Dougherty, M D

President's Address, Nathan B Van Etten, M D

Matthias Nicoll, M D, State Commissioner of Health

Louis I Harris, M D, City Commissioner of Health

William Hallock Park, M D

SCIENTIFIC PROGRAM

ARRANGED BY THE COMMITTEE ON SCIENTIFIC WORK

Andrew MacFarlane, Chairman, Albany

L Whittington Gorham, Albany

Edward S Van Duyn, Syracuse

Alfred C Beck, Brooklyn

Eugene E Hinman, Albany

Roger H Dennett, New York City

Clarence O Cheney, Utica

Arthur D Jaques, Lynbrook

Samuel J Kopetzky, New York City

SECTION ON MEDICINE

Chairman, L Whittington Gorham, M D, Albany, Secretary, Wardner D Ayer, M D, Syracuse Place of Meeting, Waldorf-Astoria

Tuesday, March 30th, 2 30 P M

"Liver Function Studies," Charles S McVicar, M D, Rochester, Minn (by invitation)

Discussion opened by Howard Shattuck, M D, New York City

"Neuron Block for the Relief of Pain With a Report as to Its Use in Angina Pectoris," George I Swetlow, M D, Brooklyn

Discussion opened by John Wyckoff, M D, New York City

"Basic Factors in Human Hypersensitive ness," Robert A Cooke, M D, and Will C Spain, M D, New York City

Discussion opened by Aaron Brown, M D, New York City

"The Recognition of Chronic Nephritis in its Early Stages, and Consideration of Some Neglected Principles in Functional Diagnosis," Nellis B Foster, M D, New York City

Discussion opened by John A Lichty, M D, Clifton Springs

"The Clinical Result After the Long Continued Use of Insulin," John Ralston Williams, M D, Rochester

Discussion opened by Nelson G Russell, M D, Buffalo

Wednesday, March 31st, 9.30 A.M.

Joint Session with Section on Surgery

"More Recent Studies Upon the Etiology of Post-Operative Pneumonitis," Allen O Whipple, M D, New York City

Discussion opened by William D Johnson, M D, Batavia

"The Experimental Production of Lung Abscess," Elliott Cutler, M D, Simon A Schlueter, M D, I F Weidlein, M D, Cleveland, Ohio (by invitation)

Discussion opened by James M Hitzrot, M D, New York City

"Pulmonary Abscess and Its Treatment" (a) from the Surgical Standpoint, Adrian V S Lambert, M D, New York City, (b) from the Medical Standpoint, James Alex Miller, M D, New York City

Discussion opened by Howard Lilienthal, M D, and John D Kernan, M D, New York City

"Broncho-pulmonary Spirochetosis," David T Smith, M D, Ray Brook (by invitation)

Discussion opened by Edward R Baldwin, M D, Saranac Lake

Immediately following the Session the Section will adjourn for the Election of Officers in accordance with Section 74 of the By-Laws

Wednesday, March 31st, 2 30 P M

Joint Session with Sections on Pediatrics and Neurology and Psychiatry

"The Vegetative Nervous System and Encephalitis with Special Reference to Personality Changes in the Young," Foster Kennedy, M D, New York City

Discussion opened by E D Friedman, M D, New York City

"The Relation of Vitamins to Disease," E V McCollum, M D, Baltimore, Md (by invitation)

"The Vitamin Value of Some Common Foodstuffs," Walter H Eddy, Ph D, New York City (by invitation)

Discussion

"A Survey of Our Present Knowledge of

Tetanus and Its Treatment," Matthias Nicoll, M D, Albany

Discussion opened by John J Moorhead, M D, New York City

Thursday, April 1st

Syphilis Demonstration for program (see page 288)

SECTION ON SURGERY

Chairman, Edward S Van Duyn, M D, Syracuse, Secretary, George E Beilby, M D, Albany Place of Meeting, Waldorf-Astoria

Tuesday, March 30th, 2 30 P.M

Joint Session with Section on Neurology and Psychiatry

"The Principles and Methods of Treatment of Fracture Dislocation of the Neck," Alfred S Taylor, M D, New York City

Discussion opened by Foster Kennedy, M D, New York City

"Ventriculometry (with Lantern slide demonstration)," K. Winfield Ney, M D, New York City

"The Diagnosis and Localization of Brain Tumors" (with lantern slide demonstration), Walter E Dandy, M D, Baltimore, Md (by invitation)

Discussion opened by S Philip Goodhart, M D, and Charles A Elsberg, M D, New York City

"Differential Section of the Trigeminal Root in the Surgical Treatment of Trifacial Neuralgia," Byron Stookey, M D, New York City

Discussion opened by Martin B Tinker, M D, Ithaca and John L Eckel, M D, Buffalo

Wednesday, March 31st, 9.30 A.M

Joint Session with Section of Medicine

"More Recent Studies Upon the Etiology of Post-Operative Pneumonitis," Allen O Whipple, M D, New York City

Discussion opened by William D Johnson, M D, Batavia

"The Experimental Production of Lung Abscess," Elliott Cutler, M D Simon A Schlueter, M D, I F Weidlein, M D, Cleveland, Ohio (by invitation)

Discussion opened by James Morley Hitzrot, M D, New York City

"Pulmonary Abscess and Its Treatment," (a) from the Surgical Standpoint, Adrian V S Lambert, M D, New York City, (b) from the Medical Standpoint, James Alex. Muller M D, New York City

Discussion opened by Howard Lilenthal M D, and John D Kernan, M D, New York City

"Bronchio-Pulmonary Spirochetosis," David T Smith, M D, Ray Brook (by invitation)

Discussion opened by Edward R Baldwin M D, Saranac Lake

Wednesday, March 31st, 2 30 P M

Election of Section Officers in accordance with Section 74 of the By-Laws

"Further Advancement in the Technique and Interpretation of Cholecystography by the Oral Method," William H Stewart, M D, and Eric J Ryan, M D (by invitation), New York City

Discussion opened by Lester Levyn, M D, Buffalo, and Merrill C Sosman, M D, Boston, Mass (by invitation)

"Muscle and Nerve Injuries Associated with Fractures," Dean Lewis, M D, Baltimore, Md (by invitation)

Discussion opened by William Darrach, M D, New York City, and Emil Goetsch, M D, Brooklyn

"Appendicitis in Early Life," Edward W Peterson, M D, New York City

Discussion opened by Richard W Bolling, M D, New York City

"The Clinical Features of Chronic Pancreatitis," J William Hinton, M D, New York City

Discussion opened by Charles G Heyd, M D, and Paul Klemperer, M D, New York City (by invitation)

"Stricture of the Ureter, Its Etiology, Sequelæ and Treatment," Cyril K. Church, M D, New York City

Discussion opened by Oswald C Lowsley, M D, New York City

Thursday, April 1st

Syphilis Demonstration for program (see page 288)

SECTION ON OBSTETRICS AND GYNECOLOGY

Chairman, Alfred C. Beck, M D, Brooklyn Secretary, Nathan P Sears, M D, Syracuse Place of Meeting, Waldorf-Astoria

Tuesday, March 30th, 2 30 P M

"The Management of Vomiting of Pregnancy," James K Quigley, M D, Rochester

"The Treatment of Eclampsia," Frederick W Rice, M D, New York City

"Prenatal Care," Asa B Davis, M D, New York City

"Fetal and Neonatal Deaths in a Series of Cases at the Lying-In Hospital," Meyer Rosensohn, M D, New York City

"Obstetrical Analgesia," James T Gwathmey, M D, New York City

Wednesday, March 31, 9 30 A.M

"The Use of the Pomeroy Maneuver in the Treatment of Persistent Occipito Posterior Position," Harry Aranow, M D, New York City

"Morbidity in Obstetrics, Its Reduction by Means of a Vaginal Antiseptic During Labor," Harry W Mayes, M D, Brooklyn

"The Treatment of Placenta Previa," Ross McPherson, M D, New York City

"Accidental Hemorrhage," George L. Brodhead, M D, New York City

"Postpartum Hemorrhage," John O. Polak M D, Brooklyn

"The Use of the Barton Forceps," William E. Caldwell, M D, New York City

Wednesday, March 31, 2 30 P M

Election of Section Officers in accordance with Section 74 of the By-Laws

"Supernumerary Ureters with Extravesical Openings," Henry D. Furniss, M D, New York City

"Radium Therapy in Carcinoma of the Cervix," William P. Healy, M D, New York City

"The Treatment of Cancer of the Uterine Body," Harold C. Bailey, M D, New York City

"Cesarean Section by a New Method," Edwin G. Langrock, M D, New York City

"Hysteroplasty (a Preliminary Report)," Salvatore di Palma, M D, New York City

"The Gestational Gland," Robert T. Frank, M D, New York City

Thursday, April 1st

Syphilis Demonstration for program (see page 288)

SECTION ON PEDIATRICS

Chairman, Roger H. Dennett, M D, New York, Vice-Chairman, Arthur W. Benson M D, Troy, Secretary, John Aikman, M D, Rochester Place of Meeting, Waldorf-Astoria

Tuesday, March 30th, 2 30 P M

Joint Session with Section on Public Health, Hygiene and Sanitation

"The Use of Convalescent Serum in the Treatment of Measles," Richard A. Lawrence, M D, Albany

Discussion opened by Rowland Freeman, Jr, M D, New York

"Etiology of Scarlet Fever," Alphonse R. Dochez, M D, New York (by invitation)

"Prophylactic Treatment of Scarlet Fever," William H. Park, M D, New York

"The Treatment of Scarlet Fever with Scarletinal Antitoxin," Francis G. Blake, M D, New Haven, Conn (by invitation)

"Active Immunization to Scarlet Fever and Demonstration of Cases," Abraham Zingher, M D, New York

Discussion by Franklin A. Stevens, M D, New York (by invitation), and Augustus B. Wadsworth, M D, Albany

Wednesday, March 31st, 9.30 A M

"A Plea for More Rational Management of the Undernourished," Frank vander Bogert, M D, Schenectady

Discussion opened by Charles Gilmour Kerley, M D, Charles Hendee Smith, M D, Louis Clausen Schroeder, M D, Dever S. Byard, M D, New York

"Recent Studies of Gonococcus Vaginitis of Infants," Edward F. Wynkoop, M D, Edgar O. Boggs, M D, (by invitation), Syracuse

Discussion opened by Walter Lester Carr, M D, Philip Van Ingen, M D, New York

"Intra-peritoneal Transfusions of Blood in the Treatment of von Jaksch Anemia," Clifford G. Grulee, M D, Chicago (by invitation)

Discussion opened by Oscar M. Schloss, M D, Marshall Carleton Pease, M D, New York

"The Indication for Ultra-violet Irradiation in Pediatrics," Alfred F. Hess, M D, New York

Discussion opened by Howard Harris Mason, M D, Royal Storrs Haynes, M D, New York

"The Role of Carbo-hydrates in the Feeding of Infants," Linnaeus E. LaFetra, M D, New York

Discussion opened by Bela Schuck, M D, (by invitation), Sidney Valentine Haas, M D, Adolph George DeSanctis, M D, New York

Immediately following the Session the Section will adjourn for the Election of Officers in accordance with Section 74 of the By-Laws

Wednesday, March 31st, 2 30 P M

Joint Session with Sections on Medicine and Neurology and Psychiatry

"The Vegetative Nervous System and Encephalitis with Special Reference to Personality Changes in the Young," Foster Kennedy, M D, New York City

Discussion opened by E. D. Friedman, M D, New York City

"The Relation of Vitamins to Disease," E. V. McCollum, M D, Baltimore (by invitation)

"The Vitamin Value of Some Common Food stuffs," Walter H. Eddy, Ph D, New York City (by invitation)

Discussion

"A Survey of Our Present Knowledge of Tetanus and Its Treatment" Matthias Nicoll M D, Albany

Discussion opened by John J. Moorhead M D, New York

Thursday, April 1st

Syphilis Demonstration for program (see page 288)

SECTION ON NEUROLOGY AND PSYCHIATRY

Chairman, Clarence O. Cheney, M D, Utica Secretary, Thomas K. Davis, M D, New York Place of Meeting, Waldorf-Astoria

Tuesday, March 30th, 2 30 P M

Joint Session with Section on Surgery

"The Principles and Methods of Treatment of Fracture Dislocation of the Neck," Alfred S. Taylor, M D, New York City

Discussion opened by Foster Kennedy, M D, New York City

Ventriculometry (with Lantern slide demonstration), K. Winfield Ney, M D, New York City

"The Diagnosis and Localization of Brain Tumors" (with lantern slide demonstration), Walter E Dandy, M D, Baltimore, Md (by invitation)

Discussion opened by S Philip Goodhart, M D, and Charles A Eisberg, M D, New York City

"Differential Section of the Trigeminal Root in the Surgical Treatment of Trifacial Neuralgia," Byron Stookey, M D, New York City

Discussion opened by Martin B Tinker, M D, Ithaca, and John L Eckel, M D, Buffalo

Wednesday, March 31st, 9 30 A M

Joint Session with Section on Public Health, Hygiene and Sanitation

"The Child as an Individual," Marion E Kenworthy, M D, New York City

"Mental Health of the School Child," William A Howe, M D, Albany

"The Organization of Mental Hygiene Clinics in the Schools of Schenectady," John E Burke, M D, Schenectady

"Method of Preventing Delinquency," Ralph P Truitt, M D, New York City

Discussion opened by Frankwood E Williams, M D, New York City

Immediately following the Session the Section will adjourn for the Election of Officers in accordance with Section 74 of the By-Laws

Wednesday, March 31st, 2 30 P M

Joint Session with Sections on Medicine and Pediatrics

"The Vegetative Nervous System and Encephalitis with Special Reference to Personality Changes in the Young," Foster Kennedy, M D, New York City

Discussion opened by E D Friedman, M D New York City

"The Relation of Vitamins to Disease," E V McCollum, M D, Baltimore, Md (by invitation)

"The Vitamin Value of Some Common Food-stuffs," Walter H Eddy, Ph D, New York City (by invitation)

Discussion

"A Survey of Our Present Knowledge of Tetanus and Its Treatment," Matthias Nicoll, M D, Albany

Discussion opened by John J Moorhead, M D, New York City

Thursday, April 1st

Syphilis Demonstration for program (see page 288)

SECTION ON EYE, EAR, NOSE AND THROAT

Chairman, Eugene E Hinman, M D, Albany
Secretary, James W White, M D, New York
Place of Meeting, Waldorf-Astoria

Tuesday, March 30, 2 30 P M

"Indications for the Radical Frontal Sinus Operations" (with lantern slides), Richard T Atkins, M D, and George Sloan Dixon, M D, New York City

Discussion opened by Cornelius G Coakley, M D, New York City

"Clinical Applications of the Functional Hearing Tests," Clayton Stewart Nash, M D, Rochester

Discussion opened by Edmund Prince Fowler, M D, New York City

"The Labyrinth Tests as an Aid in the Diagnosis of Syphilis of the Central Nervous System," Ralph Almour, M D, New York City

Discussion opened by John McCoy, M D, New York City

"Some Prevalent Misconceptions Regarding Motor Anomalies and the Validity of the Tests Used in their Diagnosis," Alexander Duane, M D, New York City

Discussion opened by Ellice M Alger, M D, New York City

"The Modern Conception of Cataracts" (with lantern slides), Arthur J Bedell, M D, Albany

Discussion opened by Martin Cohen, M D, New York City

"Systemic Otogenous Infections," Samuel J Kopetzky, M D, New York City

Discussion by Wendell C Phillips, M D, and Daniel S Dougherty, M D, New York City

Wednesday, March 31, 9 30 A.M

"Maxillary and Sphenoidal Sinusitis in Children," William Krieger, M D, Poughkeepsie.

Discussion opened by Harold M Hays, M D, New York City

"Some Unusual Effects in the Use of Cycloplegics," Edward Coleman Ellett, M D, Memphis, Tenn (by invitation)

Discussion opened by Alexander Duane, M D, New York City

Symposium on the Relation of Eye Lesions to the Non-Suppurative Nasal Accessory Sinus Diseases

Roentgenological Findings, Henry K Taylor, M D, New York City,

Ophthalmic Findings, Cyril Barnert, M D, New York City,

Rhinologic Findings and Therapeutics, Mark J Gottlieb, M D, New York City

Discussion opened by Lee M Hurd, M D, and Charles J Imperatori, M D, New York City.

Immediately following the Session the Section will adjourn for the Election of Officers in accordance with Section 74 of the By-Laws

Wednesday, March 31, 2 30 P M

Session to be devoted to special operative clinics and slit lamp demonstrations. The detailed program will be announced at opening session and on general bulletin

Thursday, April 1st

Syphilis Demonstration for program (see this page)

SECTION ON PUBLIC HEALTH, HYGIENE AND SANITATION

Chairman, Arthur D Jaques, M D, Lynbrook
Secretary, Leo F Schiff, M D, Plattsburg
Place of Meeting, Waldorf-Astoria

Tuesday, March 30th, 2 30 P M

Joint Session with Section on Pediatrics

"The Use of Convalescent Serum in the Treatment of Measles," Richard A Lawrence, M D, Albany

Discussion opened by Rowland Freeman, Jr, M D, New York City

"Etiology of Scarlet Fever," Alphonse R Dochez, M D, New York City (by invitation)

"Prophylactic Treatment of Scarlet Fever," William H Park, M.D, New York City

"The Treatment of Scarlet Fever with Scarletinal Antitoxin," Francis G Blake, M D, New Haven, Conn (by invitation)

Syphilis Demonstration for program (see this page)

Delegates' Dinner

A dinner for the delegates will be served at the Waldorf-Astoria, on Monday evening, March 29th, following the adjournment of the afternoon session of the House of Delegates Tickets for the dinner will be \$3 00

Annual Banquet

The annual Banquet will be held at the Waldorf-Astoria on Tuesday evening, March 30th, at 8 o'clock Tickets for the dinner will be \$6 00

An interesting program has been arranged Members are urged to bring their wives and to make up tables in advance

Tickets can be secured and arrangements for special parties can be made by applying to the Medical Society of the State of New York, 17 West 43rd Street, New York City

SYPHILIS DEMONSTRATION

Place of Meeting, Hotel Waldorf Astoria

Thursday, April 1st, 10 A M

Local Committee on Exhibit

Health Commissioner Louis I Harris, M.D, Chairman, Walter Brunet, M D, Louis Chargin, M.D, Howard Fox, M D, Joseph Lawrence, M.D, George M. Mackee, M D, Albert Pfeiffer, M D, Alfred Potter, M.D, Hans Schwartz, M D, William F Snow, M D, Alec N Thomson, M D, Fred Wise, M D

Tentative Program for Exhibit

Cutaneous and Mucous Membrane Syphilis

Primary and Secondary Syphilis—

From Syphilis Clinic of Bellevue Hospital
Drs M Parounagian and F Mason.

Tertiary Syphilis—

From City Hospital
Dr Benson Cannon

Syphilitic Scars—

From New York Skin and Cancer Hospital
Dr Dudley D Stetson

Visceral Syphilis

Stomach—

From Mount Sinai Hospital
Drs S Oppenheimer, B Crohn, A Winkelstein and J Marcus.

Cardio Vascular—

From City Hospital
Dr Harlow Brooks

Pulmonary—

From Vanderbilt Clinic.
Dr G Ornstein.

Bone and Joint—

From New York Hospital for Ruptured and Crippled First Surgical Division.
Drs S Klemberg, J Buchman, R. Kahle, P Colonna

Cerebro-Spinal Syphilis

Pathologic Specimens—

From Mount Sinai Hospital.
Drs I Strauss and J Globus

Tabes—

From Mount Sinai Hospital
Drs M Keschner and M Grossman

Paresis—

From New York State Psychiatric Institute.
Drs G H Kirby and A Pollack

Syphilis of Special Organs

Eye—

From New York Post Graduate Hospital
Drs A Tenner and M Troncoso

Ear—

From Beth Israel Hospital
Dr R. Almour

Congenital Syphilis

From Vanderbilt Clinic and Mt Sinai Hospital
Drs I Rosen and H Sherwood.

Early Neuro-Syphilis

From Skin and Cancer Hospital
Drs Randal Hoyt and A MacGregor

Syphilis Therapy

From Department of Health Clinic, City of New York.
Drs L. Chargin and A Stone

Pathology of Syphilis

From Vanderbilt Clinic
Dr D Satenstein.

Syphilis as Demonstrated by Radiograms

From Bellevue Hospital
Dr I S Hirsch

Experimental Syphilis

From Rockefeller Institute.
Drs Wade Brown and Hideyo Noguchi

Serology of Syphilis

The Wassermann Test—
From New York State Laboratory
Dr A. B Wadsworth

The Kahn Test—

From the Michigan State Laboratory
Dr Kahn

Demonstration of Spirocheta Pallida

From the Department of Health Clinic, City of New York.

Drs A. Jacoby, W Seckel and M. Nemser

Lantern Slide Demonstrations of—

Syphilis in the Colored Race

From the New York University

Dr Howard Fox.

Lesion Offering Difficulties in Diagnosis

From Kingston Avenue Hospital

Dr E. D Barringer

Syphilis from the Dental Standpoint

From the New York Dental College.

Dr H Winter

An exhibit of Books dealing with Syphilis, loaned by the New York Academy of Medicine.

Syphilis from the Public Health Standpoint

New York City Department of Health.

State Department of Health.

America Social Hygiene Association

Thursday Afternoon, April 1st

2 00 P M —“What Price Syphilis? William F Snow, M D, New York City

2 15 P M —“Syphilis from the Point of View of the Dermatologist,” Jay F Schamberg, M.D, Philadelphia, Pa (by invitation)

2 30 P M —“Syphilis from the Point of View of the Internist,” Udo J Wile, M.D, Ann Arbor, Mich (by invitation)

2 45 P M —“Syphilis from the Point of View of the Neuro-psychiatrist,” George H Kirby, M D, New York City

THE DAILY PRESS

MOVING PICTURES IN TEACHING

The movies have a recognized place in education as well as in recreation, but their educational value is comparatively small. Dr Sanger Brown, Chairman of the State Commission on Mental Defectives, is quoted by the New York Herald-Tribune of December 18th as saying:

"Moving pictures are undoubtedly the easiest conceivably manner of registering impressions upon the mind. To sit for hours watching a procession of visual images poured into the brain is the equivalent of bringing up a spoon-fed mind."

The principal appeal of the movies is to the emotions,—and these are of the greatest importance because they are the mainsprings of action. Motion pictures are used to only a limited extent in medical schools, even in teaching surgery. Medical students can learn from an observation of actual operations and demonstrations, and they have no need for the emotional stimulus of the pictures.

The movies have a great value in teaching public health to lay audiences. They help the laymen to visualize clinics and child welfare activities, and see the normal reactions of the sick children and the mothers. They inspire confidence and remove the dread of the unknown that is popularly associated with the ministrations of physicians and nurses. The visualization of happy faces of children strapped to Bradford frames for spinal troubles goes far toward removing from a parent the fear of the "condemnation" of a child to months of inactivity.

This is the effect of movies intelligently directed. But ordinary moving pictures are built around plots of moral abnormalities, and unpleasant situations. The villain is ahead during the greater part of the scene. Even though he is foiled at the end and right at last conquers, his near success constitutes the emphatic part of the play.

The Herald-Tribune article discusses the effect of ordinary movies on morals and, quotes Dr. Brown:

"So far I am thinking of the effect of continual attendance at the 'movies' on the normal mind. When we begin to consider the effect on the abnormal or subnormal mind, the consequences may be far more serious. It seems quite possible that some of the otherwise inexplicable crimes of the mentally weak have been committed as a result of things suggested on the screen. Slap-stick comedies, as well as detective

thrillers featuring the commission of crimes, may have their effect in suggesting similar deeds to the individual unable to discriminate between right and wrong."

"The comedian of the film knocks a man out with a length of lead pipe, and the audience laughs, the weak-minded spectator among them. We could hardly wonder if he went out afterwards and felled his pal with a similar blow, 'just because he had the notion to.' Suggestion is something that must be guarded against in the case of weak-minded citizens, and there can be no stronger suggestion than that of the actual photography of actions of humans shown on the screen."

It is fortunate that the movies have progressed beyond the stage of depicting physical suffering, although they still revel in mental and moral abnormalities, and thereby encourage the weak-minded to commit crimes. One can imagine how a sensitive woman would be affected by the exhibition of sickness and suffering, the hurried preparation of the operating room, the throes of recovery from ether, and the registration of anxiety, even though a last picture should show the patient radiant with recovered health. Few operations would be done if the unpleasant phases of surgical relief were stressed.

EVOLUTION

The New York Sun, February 8th, contains a six-inch Associated Press dispatch concerning a Chicago physician's discovery of a man without an appendix. The "discovery" itself is used featured except in the headlines, but it is not as the text for remarks on the subjects of atavism and degeneracy. The article is taken from an announcement of the Gorgas Memorial Institute, one function of which is to give out medical news in popular form.

The New York Herald-Tribune, February 20th, contains a report of an address in Cornell University, Ithaca, N. Y., by Dr. Henry Fairfield Osborn, President of the American Museum of Natural History, New York City, and one of the foremost scholars in evolution. The summarized account of Dr. Osborn's address is as follows:

"The mathematical and spiritual qualities of man cannot be accounted for by purely evolutionary processes. (Dr. Osborn) also cited the mathematical and artistic faculties as new attributes to the human race, without antecedents, and not to be accounted for by evolution. Crea-

tion occurred simultaneously with evolution, manifesting itself in the sudden origin of new attributes which have not otherwise been accounted for. French Catholic priests have been among the foremost scientists in supporting the theory, and the Catholic clergy of Louvain, Belgium, have accepted the modern scientific interpretation in its entirety."

The article further quotes Dr Osborn as follows

"The outstanding irrefutable facts are the following

"First, that man with a human form and human attributes has been on earth over 500,000 years, according to the least estimates of geologic time

"Second, that man belongs to a family of his own, called the *Hominidæ*, which has a history entirely independent of all other families for an incalculable period of time—two and a half million years at the least geologic estimate

"Third, that this human and prehuman family, composed of the existing and prehistoric races of man, has from the first divided into many branches, more or less rapidly progressive and intelligent

"Fourth, that we have indisputable records of the early dispersal of these branches in central, southern and eastern Asia, in all except the northern parts of Europe

"Fifth, that our present knowledge both of the anatomical characters and the cultural unity of even the earliest known branches of the human race, point to the descent from a single geologically remote human stock, the blood and heritage from which constitutes a prehistoric brotherhood of man

"Sixth, that convincing evidence of these outstanding facts of early human history rests on the indestructible flint and stone industry interpreted, and upon absolutely consistent anatomical evidence clearly interpreted by four generations of expert, conscientious observers drawn from the ranks of laymen, of learned professions and of the clergy, especially of the Catholic Church"

Dr Osborn clearly states the opinion of the leading scientists of the World in regard to human evolution. Physicians are interested in what may be called the creed of scientific evolutionists, for they deal with facts of physical evolution,—the appendix for example,—and also with mental evolution,—as for example, the inheritance of mental defects and criminal tendencies. Moreover, the leading students of crime believe in the superior power of the church to influence moral action, and consider it to be one of the greatest factors in crime prevention and upright living. (See this Journal, January 15, 1926, page 82)

PROPAGANDA

The New York Sun, February 11, contains an article on "Making Public Opinion", which has a direct bearing on medical publicity. It says

"In the last ten years the process of influencing public opinion through the press has passed through several stages. The oldtime press agent has gone and in his place have appeared 'publicity agents' and, more recently, 'public relations counsel'. There has been a refinement of titles and also a refinement of methods. The word propaganda is now often avoided as if it carried with it the taint of dishonesty. Propaganda reached its highest point of development during the war, attaining such sweeping success that the word became in bad odor

"We have yet to hear a really satisfactory definition of propaganda. Each piece must be judged on its merits. One initial test can be stressed. That is frankness. Publicity that attempts to conceal its source is damned at once. As a matter of fact, frankness is essential to an effective plea. Suspicion makes of publicity a boomerang"

Physicians recognize the very great value of medical publicity. The tendency of physicians is to be too frank and to magnify the author of the articles. Medical societies very properly forbid their members to make publicity of their own exploits, and some go so far as to attempt to discipline those who publish any medical article in the lay press. A few societies, such as the Medical Societies of the Counties of Kings and Bronx, have committees on publicity which offer to censor medical news for newspaper editors, and to prepare authoritative statements on medical topics, but that system is too slow and cumbersome to suit the editors

Medical societies generally recognize the propriety and desirability that physicians shall write on topics of preventive medicine, and that they shall avoid those relating to cures of established diseases. Yet there are exceptions to this rule. The standard cure of cancer is excision, and it is proper to give publicity to this fact on all proper occasions. The curative value of diphtheria antitoxin is also to be published

One of the tests of the ethics of a medical writer is whether or not the publicity conduces to the financial benefit of the writer,—whether or not it brings patients to him, or enhances his own reputation at the expense of those who disagree with him. But since physicians generally believe in the excision of cancerous tissue and in the administration of diphtheria antitoxin, educational articles advocating those procedures benefit all physicians as well as the public,—and those physicians who disagree with the accepted standards of the profession deserve their fate if the publicity leads patients to avoid them

BOOK REVIEWS

FUNDAMENTALS OF BIO-CHEMISTRY In Relation to Human Physiology By T. R. Parsons, B.Sc., M.A. Second Edition. 12mo of 295 pages. Baltimore, Williams and Wilkins Company, 1925. Cloth, \$3.00.

Of late years clinicians have been paying an ever-increasing amount of attention to the deranged metabolic processes that are so often the concomitants of disease. This chemical point of view, so to speak, is reflected in the publication of so many volumes in which clinical symptoms are explained on the basis of their metabolic etiology. The present work shows how this comparatively modern viewpoint is being embodied even in text books dealing with pre-clinical or "sub-clinical" subjects. In this volume the author discusses the chemical nature of living matter as a sort of background to the study of human physiology. He reviews the biochemistry of proteins, fats and carbohydrates and devotes one chapter to an excellent study of the pathology of carbohydrate metabolism, including, of course, a section on insulin. The latter part of the book is reserved for a consideration of some of the applications of physical chemistry to physiological processes.

The volume would be a worthwhile addition to every medical student's library.

FRANK E. MALLON

ESSENTIALS OF PSYCHIATRY By GEORGE W. HENRY, M.D. Octavo of 199 pages. Baltimore, Williams and Wilkins Company, 1925. Cloth, \$2.75.

The author has supplied the want of a concise, accurate, and literary book on psychiatry for the general medical practitioner and specialists other than psychiatrists. It is based on a rich experience gained in the foremost hospital for mental diseases. The various psychoses are accurately described, the psychoneuroses briefly discussed, and the various sociological and medical aspects of mental diseases clearly described. Nearly one-half of the manuscript is devoted to therapy. It is hoped that the book will find its way to the library of every physician who is anxious to keep abreast with the development of the various phases of medicine, for it will give a precise picture of the present status of mental diseases in general.

IRVING J. SANDS

THE HEALING GODS OF ANCIENT CIVILIZATIONS By WALTER ADDISON JAYNE, M.D. Emeritus Professor of Gynecology and Abdominal Surgery, University of Colorado. Yale University Press, New Haven, Conn., 1925. Price \$5.00.

A volume with the above title on the ancient methods of religious healing and the pagan healing gods is presented as an introductory historical study. This particular phase of the religious and social life of the ancients is seldom considered independently, but rather in connection with an introduction to the general history of medicine.

The subject is approached from a historical standpoint, all theories and controversial matters being avoided. The author has selected several of those great civilizations that preceded and overlapped the Christian era. In these nationalities, religion and healing had passed beyond the elementary stages of development, and were more or less systematized under priesthoods. These civilizations had their origin and development in an Oriental nursery, and their earliest traces are found among the Indo-Iranians and the peoples of Mesopotamia and Egypt.

Facts, traditions and myths have been gathered from archeological studies the works of classical authors and

each nationality is considered independently and under two sections the first giving a general review of the salient features of their respective religious and healing customs, and the second dealing with the personalities of their deities most intimately concerned with healing of the sick.

The people of the ancient pagan world regarded all natural phenomena, the causes of which were not apparent, as due to unseen superhuman agencies. They believed that they were surrounded by innumerable invisible spiritual beings of great variety, differing widely in character, who possessed supernatural powers by which they energized all nature, controlling its forces and directing its processes in their infinite detail.

The book is a notable and worthy contribution to the history of medicine and scholarship.

F. B. DOYLE

THE NEWER KNOWLEDGE OF NUTRITION The Use of Foods for the Preservation of Vitality and Health. By E. V. McCOLLUM, Ph.D., Sc.D., and NINA SIMMONDS, Sc.D. Third edition. Octavo of 675 pages. New York, The Macmillan Company, 1925. Cloth, \$4.25.

This is an unusual book and a hasty review of it is impossible. Although the volume of experimental data makes slow reading at times, it is necessary to develop the scientific facts set forth. The efficient condensation of an immense amount of material from the literature on dietary deficiency diseases such as beri-beri, xerophthalmia, pellagra, scurvy, goiter and rickets represents long and arduous effort. This is incorporated with an interesting discussion of these diseases. Chapters on "the diet in relation to teeth," "dietary habits of man in various countries" and "diet and resistance," are enlightening.

The facts disclosed are important not only to physicians but to the nation as a whole, for by affecting national diet a tremendous influence will be exerted in the field of preventive medicine and the building of a strong race.

After reading this book one thinks in terms of vitamins in addition to caloric values and of the quantitative relationship between calcium and phosphorus in addition to the amount of fat, protein and carbohydrate in the diet. It may be new to some that at least five vitamins having distinct protective values have been recognized.

In the reviewer's opinion it is a text book which, after the first perusal will be kept where it can be reached for frequently.

HENRY F. KRAMER

SOCIAL CONTROL OF THE FEEBLEMINDED A STUDY OF SOCIAL PROGRAMS AND ATTITUDES IN RELATION TO THE PROBLEMS OF MENTAL DEFICIENCY. By STANLEY P. DAVIES, Ph.D. Published by the National Committee for Mental Hygiene Inc., New York, 1923. Paper pp 222. Price, \$1.25.

The social control of the feeble-minded is a problem of great magnitude and practical importance. In this monograph many practical phases of the problem are particularly with regard to the institutional care of such individuals are considered. Several chapters are devoted to a description of the work done at the schools for the feeble-minded at Waverley, Mass., and Rome, N. Y. The chapter which deals with the special classes for mentally defective children in the public schools is of great practical value.

ETIOLOGY OF CANCER*

By ISAAC LEVIN, M.D.,
NEW YORK CITY

UNTIL the middle of the nineteenth century there prevailed the opinion that cancer arises in the lymph or other fluids of the body. With the appearance in 1858 of Virchow's epoch-making publication, *Die Cellularpathologie*, in which the author presented the maxim, *Omnis cellula e cellula*, the modern conception of the mechanism of tumor formation was established. With few exceptions, the cells of the adult animal or plant organism possess a very limited capacity for proliferation and are endowed instead with differentiated and highly specialized functions. A tumor cell, on the other hand, is a cell which has lost its specialization and has regained the power for proliferation which normal body cells possess only during the fetal life of the organism. This characteristic of a tumor cell is true for both benign and malignant tumors. The cells of malignant tumors, the cancer cells obtain at the same time the power of destruction of the normal tissues which lay in the path of their development and proliferation.

Virchow, who established the conception of the cellular derivation of cancer, maintained that every cancer cell, be it carcinoma or sarcoma, develops from connective tissue cells and that the latter are transformed into carcinoma cells by the aid of a metaplastic "irritation." Remak and Hiss, who established the fact that each cell in an adult organism must be derived from one of the three embryonal germ layers, held that a carcinoma cell must be derived from an epithelial cell. Thiersch, through his extensive histological studies of epitheliomata, demonstrated conclusively that a carcinoma cell is derived from an epithelial cell. He defined the cellular theory of V. as strictly by the principle, *Omnis cellula e cellula ejusdem generis*. Further investigations of Thiersch, Waldeyer and their followers, studies which continued for years, established irrevocably the fact that cancer in any organ develops from the parenchymatous cells of this organ. Secondary, metastatic tumors, where-

ever formed, are derived from the cancer cells of the primary tumor and consequently in the ultimate analysis are derived from the parenchymatous cells of the organ in which the primary tumor took its origin. In some instances, like a metastatic carcinoma of the rectum, in the brain, or a metastatic carcinoma of the breast, in a bone, the derivation is quite evident. In other cases, the metastatic tumor may differ morphologically to a certain extent from the primary tumor (metastases of a scirrhous carcinoma of the breast obtain the form of a solid carcinoma), but the derivation can always be easily traced.

The specificity of the derivation of the different types of cancer cells is subject to most remarkable refinement. Carcinoma of the cervix uteri, for instance, differs from the carcinoma of the corpus uteri from the pathological as well as clinical aspects fully as much as bronchopneumonia differs from lobar pneumonia.

The fact that the development of a tumor is due to a differentiation and proliferation of normal body cells is just as true of benign tumors as of cancer. Any hypothesis of the origin of cancer must be in harmony with this conceptions of the mechanism of formation of benign tumors.

Until the beginning of the twentieth century, cancer research was based primarily on morphological study of malignant tumors. The theories evolved as regards the etiology of cancer were not based on any experimental evidence. All the numerous hypotheses can be subdivided into two large groups. One group, to which Virchow himself belonged and which found its most astute proponent in Ribbert, maintained that any normal cell of the organism may, under influence of a certain "metaplastic irritant," be transformed into a cancer cell. The other group with Cohnheim at the head, held that cancer can develop only through the activity of a group of cells which retained in a dormant state the characteristics of fetal life, a group of cells which represented a so-called "embryonic rest."

All these hypotheses are predicated on the con-

The other group with Cohnheim at the head, held that cancer can develop only through the activity of a group of cells which retained in a dormant state the characteristics of fetal life, a group of cells which represented a so-called "embryonic rest."

All these hypotheses are predicated on the con-

* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse on May 12 1925

ception that cancer is a type of neoplasia. In order to evaluate correctly the results of the more recent experimental and clinical cancer research which will be discussed later, it is necessary to analyze the relationship between cancer and other types of neoplasia as they occur in adult animal and plant life.

THE RÔLE OF NEOPLASIA IN ANIMAL AND PLANT PATHOLOGY

Neoplasia occurs in adult life of an organism to aid the needs of physiological function of an organ (spermatogenesis, lactation, formation of placenta, etc). It further takes place either as a *reactive* new tissue formation to protect the organism against noxious agents or as a *reparative* neoplasia to replace lost tissue. The difference between these types of neoplasia and formation of cancer consists in the fact that the former types of neoplasia continue only as long as it is necessary to accomplish the work of protection or repair and then cease. The endless proliferation of the cancer cells, on the other hand, serves no good purpose to the organism and ultimately destroys it. It is possible to conceive a priori that other types of neoplasia may gradually change into malignant new growth.

The relationship between the reactive neoplasia and formation of malignant tumors in plants was the subject of a series of investigations of the writer in collaboration with M. Levine. The research was done on crown gall, club root of cabbage, and on potato "wart." In order to understand the results obtained, the difference in the structure of an animal and a plant organism must be taken into consideration. An animal organism reacts frequently to an attack of any injurious agent with the so-called *inflammatory* processes, which are accompanied by activities of the lymphoid tissues and proliferation and migrations of lymph cells. These cells and tissues offer the necessary protection and destroy or neutralize the noxious agent. Subsequently, the repair of the injured tissue and formation of a scar is also done by the lymphoid tissue. Even the highest organized plants do not possess any specialized lymphoid tissue. The main method of self-protection of a plant against an injury is the proliferation of the cells of the region which was subjected to the injury. The investigations of the writer have shown that in plants, as a result of a parasitic invasion, there forms a benign tumor which is analogous to a granuloma in an animal organism. A small fraction of these benign tumors-granulomata may be directly transformed into biologically malignant tumors. Similar conditions will be shown later to exist in animal pathology.

INOCULABLE ANIMAL CANCERS

The ultimate elucidation of the mystery which surrounds the transformation of any type of

neoplasia into cancer was brought a great deal nearer by the experimental cancer research of the last quarter of a century.

In 1901, Jensen showed in a very complete and exhaustive study that he succeeded in transplanting a mammary carcinoma of a white mouse into other white mice. He continued to reproduce from generation to generation of mice with equal success. This research was the beginning of experimental cancer research which continues throughout the world to date. The inoculations consisted in the introduction into the subcutaneous tissue of the axilla of the animals either of an emulsion of the tumor or of a small piece of tumor tissue.

The basic conception for this whole field of experimental cancer research is the most generally accepted idea that the tumors of white mice and white rats are analogous to human cancer. Some investigators, however, notably von Hanseemann, maintained that there is no analogy between these tumors and human cancer. He bases his opinion on the following differential characteristics between the two conditions: (1) Human cancers never reach as large a size in proportion to the body weight as do the tumors in animals. The only tumors that reach such a size in man are benign growths. (2) Animals do not suffer constitutionally from the tumor, i.e., the state of cachexia is not observed. (3) The tumors in the mouse and rat appear as movable encapsulated nodules, which are easily removed surgically and do not recur after the operation. (4) A true metastasis does not take place in these animals. Conditions described as metastasis are simply multiple inoculations. When an emulsion of the tumor cells is injected subcutaneously, part of it may enter a blood vessel and thus reach some distant part of the animal and form there a second tumor, which is, consequently, not a metastasis. (5) The inoculated tumors frequently retrocede, whereas human cancer does not. The apparent spontaneous cures described occasionally in human beings are due usually to a wrong diagnosis. (6) Morphologically, the animal tumors resemble endotheliomata most nearly, and while it is not possible to prove absolutely the endothelial nature of the growth, the growths are not analogous morphologically to human carcinoma.

In his discussion von Hanseemann apparently had in mind mainly the tumors artificially inoculated into previously healthy animals. In order to gain a true conception of the nature of the animal tumors, the analysis must begin with the spontaneously occurring tumors from which the material for the inoculation is taken.

The number of the morphologically different forms of these tumors that have been described in animals is nearly as great as the number of human cancers. Jobling described cases of adenocarcinoma, cystadenoma, alveolar carcinoma,

and sarcoma. Haaland described carcinoma of the preputial gland, adenocarcinoma of the kidney and ovary, spindle-celled, round-celled, and polymorphous celled sarcoma, melanoma, and fibromyoma of the uterus. It is evidently impossible to classify all these tumors as endotheliomata.

The best proof of the fact that these spontaneous tumors are malignant is the comparative frequency of the occurrence of metastases. Murray, in a study of sixty-eight mice with spontaneous tumors, found metastasis in the lungs in twenty-seven cases, and in the lymphatic glands in three cases. In studying twenty-six animals Jobling found metastases in five, and Haaland, in a study of 273 animals that had spontaneous tumors, found nodules clearly visible to the naked eye in the lungs of 38 per cent of them.

Furthermore, most of the clinical characteristics of these tumors clearly indicate that the animals are suffering from a malignant disease. According to Haaland, the average duration of life of the animals after the tumor has come under observation is about six weeks.

What is still more conclusive is the fact, also observed by Haaland, that in 54 per cent of the animals with spontaneous tumors, the tumor recurred after an apparently radical operative removal. The same phenomenon was observed by Clunet. There can be no doubt, therefore, that a spontaneous tumor in a white mouse or white rat is malignant and consequently not only morphologically but also biologically analogous to human cancer.

It is impossible to define what is to be considered a condition of cachexia in these animals. The fact, however, that the animals die in the short period of about six weeks after the tumor is discovered, shows that the general health of the animal must have been deeply affected by the growth of the tumor.

Tumors artificially reproduced through inoculation in previously normal animals are of greater value for the experimental study of cancer than the spontaneous tumors. The reason is that the latter are comparatively rare, while inoculated tumors may be obtained in any desired number. These artificial tumors apparently seem to differ widely both from the spontaneous tumors of the same animals and from malignant growth in man. Although the material used for the inoculation is taken originally from a spontaneous tumor, i.e., from an animal suffering from a malignant growth, the tumor that develops in the new host seems to be of a more benign character when the transfer is made by a subcutaneous inoculation. As a result of this inoculation there forms under the skin a growth which may reach a very large size. In the majority of cases this tumor is circumscribed, movable, and encapsulated. It usually does not infiltrate the surrounding tissue, it never infiltrates bone, peri-

toneum, or the pleura, and very seldom infiltrates the fascia and musculature underlying the skin. The skin itself, however, may become adherent to the tumor and ulcerate. Upon complete surgical removal the tumor does not recur as does the spontaneous tumor. Thus, the inoculated tumors apparently resemble benign growths rather than true cancers. In order to study the true behavior of the inoculated tumor and its influence on the general state of health of the new host, the writer has undertaken a series of investigations with inoculation of these tumors into internal organs.

For the inoculation into organs the writer employed the white rat mainly. Two tumors served for the inoculations: a spindle-celled sarcoma of the white rat, and an adenocarcinoma described by Flexner and Jobling. The tumors were inoculated into the brain, testicle, kidney, spleen and liver. The organ was reached through an abdominal or lumbar incision, or by trephining the skull to reach the brain, and then a small piece of the tumor was placed in the center of the organ by means of a trocar needle. The bleeding even in the liver was minimal and ceased very soon. The abdominal or lumbar incision was then closed by a silk suture. The trocar needle does not cause any permanent injury to the organ.

When the tumor, placed inside an organ, fails to grow, it is with difficulty that one can notice any change in the region where the tumor graft was placed, either by gross inspection or by microscopical examination. Consequently, whatever local change is found in the region of the organ surrounding the growing tumor is caused not by a mechanical injury through the operation but by the interaction between the organ cells and tumor cells.

In order to compare the effects produced by inoculating a tumor into one of the organs of a susceptible animal, with the effects seen in human beings suffering from cancer, it is well to recapitulate the salient characteristics of malignant tumors. These characteristics are (1) rapidity of growth, (2) peripheral extension, lack of capsule, and invasive infiltration of the surrounding tissue, (3) tendency to develop metastases and to recur after removal, and (4) cachexia and clinical malignancy.

The tumors produced by inoculation into organs were analogous to human cancer of deep seated organs in every detail. It did not grow to as large a size as the subcutaneous tumors grew invasively, formed metastases and killed the animals in from 6 to 12 weeks.

IMMUNITY IN CANCER

The most important phenomenon observed in the study of experimental cancer consists in the so-called immunity or resistance of certain animals to the growth of the inoculated tumors.

This resistance depends upon a number of various complex conditions. The phenomenon is a resultant of two component parts (1) *the power of the inoculated cancer cell for unlimited proliferation* and (2) *the reaction of the organism of the host*. When a spontaneous tumor is inoculated it grows successfully only in a small number of animals used, frequently in less than 10 per cent. In subsequent inoculations with material taken from the implanted tumors the cancer cell increases *its proliferating power—its virulence*. The same is true of metastatic tumors in the human. The fact, on the other hand, that a certain number of animals always retain their resistance to the tumor growth shows *the influence of the reactivity of the host*.

Many interesting phenomena relating to resistance of the host to the growth of the malignant tumors were noted by the writer through his method of inoculation into organs. The phenomenon of the greatest importance from both the theoretical and practical standpoint, is the condition of local organ resistance which the writer has demonstrated by this research method. In the experiments with an adenocarcinoma of the white rat, discovered by Flexner and Jobling, the writer observed that while the tumor grows when inoculated subcutaneously or into any other organ in a large percentage of animals used, it does not grow when inoculated into a normal testicle.

This failure of the growth of the tumor in the normal testicle is not due to a general condition of the organism, but to a local action of the testicle on the tumor cells. The percentage of animals which are generally resistant to a subcutaneous inoculation of this adenocarcinoma is very small, therefore all the animals used for the inoculation into the testicle could not have been resistant to the growth of the tumor, nor was the failure due to the mechanical influence of the tunica interfering with the expansion of the organ by the growing tumor, since other types of tumors grow readily in the testicle. The mechanism of this local resistance can thus be due only to an inhibitory action upon the cells of this tumor by the parenchymatous cells of the testicle.

PRECANCEROUS STATES

(a) *Experimental Evidence* In 1913, Fieger reported on a series of experiments which consisted in feeding rats with cockroaches infected with a nematode. These rats developed in the stomach *inflammatory conditions, papillomata* and in a certain number of cases *true carcinomata* with formation of *metastases*. The carcinomata were inoculable.

About the same time Yamagiwa and Ichikawa, two Japanese investigators, reported that they succeeded in artificially producing malignant epitheliomata of the skin by painting the skin of

the animals—rabbits and rats—with coal tar and its derivatives. Since then a great deal of similar work is being done all over the world.

These investigations represent a step forward in experimental cancer research since it proves that cancer may be produced artificially by known means. The correct analysis, however, of the results obtained must take into consideration two facts. (1) That the irritation must be continued for a long time. Eight months of treatment of a rat corresponds to about twenty-five years of treatment in a human, since the life cycle of a rat is only two years. (2) Only a small fraction of the number of animals experimented upon (10% to 25%) develop true malignant tumors, while the rest of the animals show at best only *precancerous* conditions. The significance of these two facts will be discussed later.

In the ultimate analysis the results consist in the following. The parasitic or chemical irritants produce a *precancerous condition* or in other words a *favorable soil* on which either an inoculable or a spontaneous malignant tumor develops. In this respect the results are analogous to an artificial production of a precancerous state which the writer reported in 1912. As was stated above, in a white rat susceptible to the growth of a Flexner-Jobling carcinoma, when inoculated subcutaneously or in any other organ, the tumor does not grow when inoculated in the testicle. In a series of animals the writer treated the testicles before inoculation with the tumor with injection of Scharlach-R Oil or a 4% mixture of sulphuric ether in water. As a result of this treatment there was noted an injury of the parenchymatous tissue of the organ and formation of inflammatory connective tissue. Inoculation of the Flexner-Jobling carcinoma in such testicles was successful. In these experiments, like in the experiments with parasites or the coal tar products, the soil was made favorable for the development of cancer. A *precancerous state* was created.

(b) *Clinical Evidence* There has accumulated, of recent years, a vast amount of clinical evidence of a direct relationship between chronic irritation continued for years and formation of cancer. East Indians, who use Kangri stove, develop epithelioma of the skin of the abdomen on the basis of a dermatitis produced by the stove. The eastern women, who constantly chew betel-nut, develop epitheliomata of the cheek in the exact area in which the betel-nut was kept. Dr. A. Scott made an exhaustive study of the occupation dermatoses of the paraffin workers of the Scottish shale oil industry. A certain number of the workers develop epithelioma following these occupation dermatoses. Workers in aniline dyes factories develop cystitis and subsequently carcinoma of the bladder. Carcinoma of the bladder infected with bilharzia, Piget >

disease of the nipple, epithelioma arising on the basis of an X-ray dermatosis, are other instances of the same kind. This clinical evidence leaves no doubt that continued chronic irritation acts as a precancerous condition and prepares a favorable soil for the development of cancer. A very interesting case came to our clinic recently in which an epithelioma developed on the basis of a tuberculous skin ulcer. The case will be reported elsewhere. The writer has shown in his clinical investigations that Hodgkin's disease begins as an infectious granuloma and then subsequently develops into a true lymphosarcomatosis.

As was shown above for the chronic irritations produced artificially in animals the same two conditions must be noted for the chronic irritations acting as precancerous states in the human, namely the irritations must continue for a long period of time, and only in a small percentage of cases does cancer actually develop.

EVALUATION OF THE PARASITIC THEORY OF CANCER

The search for a specific microorganism as the etiological factor in cancer began forty years ago immediately upon the discovery of the parasitic origin of infectious diseases. An amazing amount of work was done on the subject. In the majority of instances the specific organism upon further investigation proved to be an innocent saprophyte.

In 1907, E. F. Smith showed that the disease of plants called crown-gall—tumor-like in nature—could be reproduced artificially by an inoculation of a normal plant with a pure culture of a bacillus which he called *Bacterium tumefaciens*. Smith maintains that this or a similar disease can be produced only by this particular organism, that all other tumor-like formations observed in plants due to other parasites, like *Plasmiodiophora brassicae*, are entirely different pathological entities, and that only crown-gall is a true plant tumor. In his estimation this tumor is practically identical biologically with animal and human cancer. Since crown-gall is caused by the action of the bacterium described by him, he concludes in one of his recent articles that "to a biologist the conclusion is almost irresistible that human cancer must be due to a parasite and that one parasite may well be the cause of the most diverse forms, as we have seen to be the case in plants." This deduction is so sweeping in character, so far reaching in its generalization, and the results of Dr. Smith's work have become so widely known and quoted by the medical profession that it has seemed to the writer to be desirable to renew his investigations to analyze the material from the viewpoint of animal pathology, and to attempt to determine the true analogy between the crown-gall and animal cancer. The investigation is stated above, was

done in collaboration with a botanist, M. Levin.

The results obtained may be briefly summarized as follows. Crown-gall is undoubtedly a *neoplastic disease* and the pathogenesis of the condition consists in an abnormal proliferation of a group of cells. It must again be reiterated however that in comparing new growth in animals and plants one must take into consideration the fact that an adult vertebrate is not capable of reproducing complete organs, while the highest plants may and do constantly reproduce with ease all their organs, leaves and branches as well as roots. Reproduction of parts of the organism, and consequently cell proliferation, is a function of an adult plant which may be induced with the greatest of ease. It is self-evident that since an adult plant cell proliferates so as to reproduce an organ, a young crown-gall cell may do likewise. This characteristic of a normal plant cell explains the striking phenomenon, not encountered in any neoplastic disease in the animal, that a crown-gall may form within its own cells, or rather as a transformation of its cells, not only adult differentiated tissues (parenchyma) but even rudimentary organs (conducting system) or a whole rudimentary organism (leafy shoot). All these various types of structures found in a crown-gall do not indicate, as appears to be the opinion of Smith, that the crown-gall is analogous to all the types of human cancer, but rather that it is different from any type of animal tumor.

In order to formulate clearly the position which the crown-gall occupies among the neoplastic diseases, one must take into consideration the fact that the crown-gall is usually a benign condition and only rarely does it act in a manner analogous to a malignant tumor in an animal.

The true mechanism of the formation of the benign crown-gall can be conceived only in the light of the difference in the structure of an animal and plant organism. An animal organism, as was stated above, reacts frequently to an attack of an injurious agent with the so-called inflammatory processes, which are accompanied by certain activities of the lymphoid tissues and proliferation and migrations of lymph cells. These cells, and not the special tissues of the injured region offer protection, envelop and destroy the injurious agent or neutralize it. When the latter is destroyed the inflammatory process ceases and functions of repair or replacement of the injured tissue take place. This repair, which ends in the formation of a scar, is a type of neoplasia which differs radically from tumor formation. It continues just as long as is necessary to replace the lost tissue and then ceases, while a malignant tumor is a neoplasia which has no reason for its formation in the needs of the organism and has no finality in its development.

Even the highest organized plants do not pos-

sess any specialized lymphoid tissue to take care of the functions of the protection of the organism against an injury or of the repair of the injured or lost tissue. One of the methods of protection of plants against injury consists in the presence of a cellulose wall. It seems plausible to suppose that as a matter of self protection a plant may respond to an injury by a proliferation of the cells of the region which was subjected to the injury. The small wart-like galls, which grow very rapidly for a time and then remain stationary, as the writer has observed in a number of instances, are products of such functions of repair and protection and do not represent true tumors.

Thus a small benign crown-gall is a condition analogous to *granulation tissue and a scar* in the animal organism. A crown-gall which grew to comparatively large size and still does not affect in any way the general welfare of the plant may be compared to a benign tumor in an animal, but is probably more nearly analogous to a large *callus*, which develops after a fracture of a long bone, or to a *cheloid* in the human.

Smith ascribes a great deal of importance to the phenomenon of development of leafy shoots in a certain number of crown-galls, and considers this type of gall to be identical with human embryoma. This finding he considers the main proof for his contention that all types of human cancer may be reproduced in plants by the aid of the *Bacterium tumefaciens*. In the opinion of the writer there is no analogy between a human embryoma and the crown-gall with a leafy shoot sprouting from it. An embryoma is a growth consisting of an irregular combination of various fetal tissues. It is more akin to a malformation than to a true tumor. A malignant tumor may develop subsequently within an embryoma in the same manner as it develops within normal tissue. The leafy shoot, on the other hand, appears on a fully developed crown-gall and is identical with a shoot which develops in a normal part of a plant. It simply indicates that crown-gall tissue, as well as normal plant tissue, may reproduce complete organs and thus still more widens the gap between the animal tumors and the crown-gall.

The malignant type of crown-gall is undoubtedly quite analogous to animal cancer. This malignant transformation takes place, however, rarely as is seen from the results of the field studies on sugar beets of Townsend, who found that the destruction of the beets by the gall is not sufficient to influence the tonnage of the crop. Furthermore, this transformation is not related directly to the function of *bacterium tumefaciens*.

A spindle cell sarcoma of a fowl was described by Rous, which is apparently analogous to other malignant animal tumors. The tumor infiltrates and destroys the surrounding tissues and metastasizes in the internal organs. The inoculated

animals emaciate and die within three weeks after the inoculation. This tumor can be propagated not only by inoculation with fresh living sarcoma tissue, but also by means of tumor filtrate passed through a Berkefeld filter. In the white mice and rats described previously, it required the placing of viable cancer cells into a normal animal in order that a new tumor might develop. In the chicken sarcoma, on the other hand, an injection of a tumor filtrate, which cannot contain living cancer cells, but only either a chemical agent or an ultramicroscopic organism, is followed by the development of the identical sarcoma in the new host.

An investigation was reported recently by J. W. Nuzum which consisted briefly in the following. He obtained from human breast cancer as well as from inoculable tumors of the white mice, a micrococcus of the streptococcus group in pure culture. He treated 72 mice with this culture in the same manner as animals are being treated at present with chemical or parasitic irritants, giving as many as 62 treatments in the course of four months. These treatments resulted in epithelial proliferations of the skin. A malignant tumor did not develop in a single animal. Fifty mice were treated in the same manner with cultures of streptococcus pyogenes and staphylococcus albus. These latter animals either died of septicaemia or developed abscesses. Ten bitches received bi-weekly injection of the culture of a micrococcus obtained from a human breast for a period of six months. A number of the dogs developed chronic cystic mastitis and one old dog developed a carcinoma with metastases. A man seventy years old, suffering from epithelioma of the cheek, was treated with the same culture for four and a half months three times a week over the skin of the right groin and an epidermoid cancer developed at the area of the skin area treated. Nuzum concludes as follows: "While the results of these inoculations may be interpreted differently and the explanation of a chronic non-specific irritation brought forward, the obvious fact cannot be denied by those entitled to an opinion that genuine cancer with metastases has been produced in the dog and primary cancer in man by repeated inoculations of pure cultures of the microorganism so constantly present in human breast carcinoma."

It seems to the writer that any proof of specificity of the microorganism is lacking in the experiments of Nuzum. The results obtained on the mice is most probably due to the fact that his microorganism is a saprophite and therefore acted in a manner identical to paraffine, soot or any ordinary irritant would have acted, while the pyogenic microorganisms which he rubbed into the fifty mice were pathogenic and produced septicemia or abscess.

Nuzum himself quotes Goodpasture, who

found in 2% of old dogs spontaneous malignant breast tumors. The burden of proof that the formation of the cancer in the only dog was not a coincidence rests on Nuzum, and in order to prove the specific action of the microorganism on the human skin, Nuzum should have done a control experiment by rubbing into another skin area paraffine, soot or any other chemical irritant for the same length of time in order to ascertain that a similar epidermoid cancer would not develop.

Meanwhile, F. Blumenthal of Berlin reports that he succeeded in isolating from human breast in a pure culture a microorganism similar to the *Bacterium Tumefaciens* of E. F. Smith and that he succeeded in obtaining with it inoculable tumors of white rats.

Now what is the true etiological relationship between these innumerable parasites and cancer? Which of these parasites is specific or are they all specific? Has it been proven that there exists a class of parasites which incites normal organ cells to proliferation, the so called bacterium *neoformans* of Doyen or bacterium *tumefaciens* of Smith?

Smith, discussing the tar cancers, states as follows: "The tar treatments involve a long continued open wound subject to and inviting all sorts of infections, so that if there were a cancer parasite in the environment of any of these animals, either in the soil, or in the litter, or on its food, or on its skin, or on the walls of the cage, or in the dust of the room, or on the hands of men handling the wounds, it would be more or less certain to find lodgement and a very favorable nidus in these irritated raw places."

The possibility of omnipresence of a specific microorganism causing the formation of all types of cancer cannot be denied offhand. However, the behavior of such a hypothetical organism would have to be different from that of any parasite known to date. All pathogenic microorganisms investigated thus far produce a destructive degenerative effect on the cells of invaded tissues. This effect may be accompanied by reactive neoplasia of the lymphoid tissue. It is conceivable that such a purposeful reactive neoplasia may gradually change into malignant neoplasia of the local connective tissue when the soil of the host is favorable. The pathogenesis of sarcoma particularly lymphosarcoma, Rous' chicken sarcoma, as well as the plant tumors, as was shown above, may be closely related to the preexisting reactive neoplasia caused by a parasite. In other words it is difficult to prove that in connective tissue cancers the secondary tumors are metastatic and are not created anew in the distant regions through the action of an invisible parasite on the connective tissue of the new location. A metastatic adenocarcinoma of the rectum, in the brain, however, cannot be

conceivably created from any of the cells of the latter organ.

The action of a hypothetical cancer microorganism can be conceived only in one of the following two ways. Either the organism acts on the first group of organ cells, changes them into cancer cells and then ceases its function. In this case the action of the parasite would be subordinate to the cellular function and would not differ from a non-specific chemical irritant. The proliferative power of cancer cell itself would be the true cause of cancer. Else the constant presence and action of the parasite is needed for the formation of the primary as well as the secondary malignant tumors. Such a parasite would have to live in symbiosis with the cancer cell, divide simultaneously with the latter and migrate together throughout the organism of the host, in a word, must submerge its life and function with the life of the cancer cell. The most striking instance of such a dominance of the cellular as against parasitic characteristics of cancer is presented by the behavior of two primary cancers in the same individual. The occurrence of double primary malignant tumors in the same patient is more common than was thought previously. Each primary tumor produces its own metastatic tumors in different organs. Examination reveals two types of metastatic tumors differing from each other and resembling their own primary tumors. A parasitic action causing such refined cellular specificity and differentiation is difficult to conceive. The phenomenon is undoubtedly due to the innate autonomous characteristics of the different somatic cells which have become changed into cancer cells.

It seems to be easier for the human mind to think in medicine in terms of parasites and extrinsic irritants and noxious agents than to fathom the intricacies of endocellular functions and to estimate the fundamental laws governing cellular proliferation and growth under normal as well as pathological conditions.

THE RÔLE OF INHERITANCE IN CANCER

An analysis of all the available data of the causation of cancer indicates that the formation of a malignant tumor is the resultant of three factors. (1) The innate power of every normal cell to proliferate. This fact, that any normal cell relieved from the restraint of the rest of the organ begins to proliferate, has been conclusively proven by the successful cultivation of normal as well as cancer cells in vitro. (2) An irritant which initiates the proliferation of cells for the purpose of protection and repair. (3) Lack or weakness of those inhibiting powers of an adult organism which keep in check all its normal tissue cells against purposeless malignant proliferation.

While the second factor is extrinsic in its

nature, the first and third factors are inherent characteristics of all living organisms. It is plausible to suppose a priori, therefore, that these latter factors in causation of cancer may be characteristics transmitted by inheritance to subsequent generations.

The problem of inheritance in cancer has been occupying the minds of investigators for a long time. The results were rather unsatisfactory. With the advent of the modern science of genetics, which is based on the fundamental laws of inheritance discovered by Mendel in 1865, the subject of inheritance of cancer was taken up anew.

The writer has shown in 1910, in a series of experiments, that the offspring of rats immune against the inoculation of a tumor is partly immune and partly susceptible to the inoculation. The ratio between the number of resistant and susceptible animals seemed to correspond with the Mendelian laws and also seemed to indicate that the inherited power of resistance is a dominant unit-character in accordance with the terminology of Mendelian genetics. Similar conclusions were derived at by Maud Sly in her studies of inheritance of spontaneous tumors of mice. Th H Morgan and his pupils have discovered a malignant tumor of the fruit fly (*Drosophila melanogaster*) which is transferred by inheritance in conformity with Mendelian laws. The writer made a study of the influence of heredity in human cancer by the aid of an analysis of the collected data in accordance with the Mendelian laws of eugenics. A number of families were studied for several generations back. The analysis of the material shows that the incidence of cancer in these families is not greater numerically than would be found among the population of the community as a whole. But there are several points in the analysis, which indicate that cancer may be influenced by heredity. A cancerous fraternity, i.e., a fraternity in which one or more members suffer from cancer, usually shows in a previous generation a cancerous member either on the paternal or maternal side or both. In other words, a cancerous fraternity is usually derived from the union of two germplasms, each of which is characterized by the presence of germ cells that are non-resistant to cancer.

The further conclusion may be drawn from the analysis of the results obtained that resistance to cancer is a dominant character whose absence creates the susceptibility to cancer. Another general inference may be made from the investigation that the susceptibility is specific in different

families for different organs. One family showed a preponderance of the cancer of the uterus in the female members, while another was characterized by cancer of the breast.

The most important result of the investigation thus far consists in the fact that it shows the importance of the presence of an inherited resistance to cancer growth. It may be of the greatest benefit for the future study of the subject of cancer to bear in mind not the fact that *one out of ten* persons who reach the cancer age suffers from the disease, but that *nine out of ten* remain immune.

It is very significant in this connection that an analysis of all the material experimental as well as clinical, obtained in the study of the relation of chemical or parasitic irritants on the formation of cancer, show the same results. Namely, of the whole number of animals used or the clinical cases investigated, only a comparatively small percentage develops cancer. This successful fraction generally ranges somewhere between 10% and 25%. This is rather close to the main fundamental Mendelian law that in the second generation there appear 75% with dominant unit characters and 25% recessive.

CONCLUSION

An investigator in any branch of the domain of science must always be ready to revise completely his conceptions when a new discovery is made. At the same time, without a working hypothesis, it is impossible to pursue scientific investigations.

The sum total of our knowledge of the causation of cancer to date make the following conceptions to be the most plausible. (1) Attempts of formation of cancer in any organism is frequent but the greatest number of people (not less than 75%) have an inherited capacity to resist the formation of cancer. (2) The human society is so inbred that every family has a certain number of members in one generation or another with an inherited susceptibility and further intermarriage cannot alter the situation. Consequently, for practical purposes, inheritance does not increase the chances of an individual to control cancer. (3) Without an additional local irritation of some kind, cancer may not develop even in a susceptible individual. (4) The most promising field in cancer research is the study of the conditions which favor the formation of cancer and the methods for their correction.

SURGICAL EXPOSURE OF DEEP-SEATED INACCESSIBLE NEOPLASMS FOR A PROPER IMPLANTATION WITH RADIUM EMANATION IN CAPILLARY GLASS TUBES BY THE BASAL ROUTE

By PAUL E. DURHAM, M.D.,

NEW YORK CITY

RADIUM emanation or Radon is a gas formed by the disintegration or breaking down of the radium atom (radium salt or element). This emanation is collected in long glass capillary tubes several feet in length, each of these tubes are then cut with a flame into bare tubes or seeds approximately 3 to 5 mm in length for practical purposes. But for more delicate work such as laryngeal implantation they are made as small as possible, i. e., as low as 2 mm in length. The usual sizes vary from 3 to 4 mm in length and 0.3 to 0.4 mm in diameter while the more minute ones are only 2 mm in length and 0.3 mm in diameter. These tubes are buried in the tumor and left permanently.

The quantity of emanation encased in each of these bare tubes depends upon the particular features of the tumor to be treated and upon the histopathological changes desired, whether a caustic effect with ulceration or a more gradual devitalization of the neoplasm with replacement by fibrous tissue. The writer prefers the latter method and wishes to avoid ulceration and slough with its attending sequele. And to accomplish this I am using seeds which as a rule vary from 0.3 to 0.6 mc. A millicurie of emanation is the quantity of emanation in equilibrium with one milligram of the radium salt. It supplies 132 millicurie hours of radiation to the surrounding tissues when embedded before it has become inactive. That is the same amount of radiation which would be given off by leaving one milligram of the radium salt deposited for 132 hours.

In reply to the question so often asked, "Do these bare tubes act as foreign bodies and cause trouble later?" We will state that we have never observed any bad results after implantation in a comparative large number of cases.

So far in the range of literature, the writer is unable to find one single article definitely laying down these four cardinal principles, namely surgical exposure of the tumor base, partial ligation of the arterial supply, bimanual palpation, and implantation with radium emanation bare tubes by way of the aseptic surgical wound of approach for the purposes of treatment of deep seated inaccessible neoplasms in general.

The step taken by Beck, partakes somewhat of the same nature as that which is proposed in this paper. The difference lies in the fact that Beck proposed to excise the growth or that part which was possible, and then treat with roentgen radiation or with filtered radium in metal tubes leaving the wound open to granulate in. The present paper is not concerned with partial surgi-

cal eradication, but with surgical exposure of the tumor from the "basal side" for purposes of palpation, arterial ligation and implantation with unfiltered radium emanation followed by sewing up the wound after this is accomplished.

I wish to make plain, that without any previous application of radiation, my plan is to (1) deliberately expose the basal structures of the tumor surgically, (2) ligate the main arterial supply to the involved lesion, (3) palpate the extensions with the fingers of each hand placed on the opposite sides of the tumor, and (4) follow with the distribution of radium seeds into the neoplastic field by inserting the implant needles through the base of the growth using the fingers on the opposite side of the tumor to guide the needles into the tumor and its extension.

An example of the application of these four cardinal principles in the treatment of deep-seated inaccessible neoplasms will be found described by myself in the May 20th issue of the *Medical Journal and Record* of this year, entitled "Intra-peritoneal Implantation of Cervical Carcinoma."

The following discussion will make it apparent that the use of all these principles combined is limited to the treatment of several organs most commonly involved but that the first principle in conjunction with two or even one of the others is often found justifiable if not demanded.

Many of the diverse methods heretofore described of applying radiation to neoplasms with associated surgical procedures err in principle because they are based upon

(1) The direct application of radiation to the external or superficial surface of lesions which are too deeply infiltrated to be efficiently radiated.

(2) The less precise or blind method of insertion of the implantation needles directly through the external surface of tumors with deep infiltrations, which can only be determined by surgical exposure.

Sufficient emphasis has not been laid upon surgical exposure of the basal structures of the tumor for the purposes of arterial ligation, bimanual palpation and implantation by the basal route.

Partial ligation of the arterial supply to the region involved has either been shelved to a great degree until the radium slough with impending hemorrhage no longer permitted delay or is performed at the time of treatment of metastatic glands at a late date. And the literature is still more barren in reference to the main item of this paper, i. e., the deposit of bare glass tubes of radium emanation throughout the tumor proper

and the circumscribing tissues, by inserting the implant needles under guidance of the eye through the aseptic surgical base of the wound using the fingers of the opposite hand on the outer surface of the growth to act as a guide to direct the implant needles accurately in the carcinomatous infiltrate and surrounding questionable tissues precisely as desired

Surgical exposure is the only means of bringing many deep seated neoplasms into accessible ones. This exploratory approach affords the opportunity to ascertain by sight and palpation the limits of extension of the growth which is essential if the neoplasm is to be implanted accurately with the distribution of bare tubes of radium emanation to all parts of the involvement. The

No 1—Method of palpation of tumor

accessibility so brought about permits the operator to insert the implant needles under guidance of the eye through this exposure into all parts of the growth, at the same time to direct and guide these with the opposite hand. This is especially advantageous in the intra-abdominal implantation of cervical carcinoma since the injury to the ureters and large vessels is very liable when attempts are made to implant blindly from below. Also in the implantation of tongue and floor of the mouth lesions with metastatic involvements of the upper neck which lie in close apposition to the jugulars, carotids and their large branches. I am at a loss to see where any radical step is taken in this method of attack since the growth is not disturbed, and the chances of metastasis are not increased because the line of incision for this surgical exposure does not pass through cancerous tissue but is removed for some distance. The time required for performing these several steps is much less than that for complete resection.

The incision for the exposure in every case should be so devised as to pass through healthy tissue yet afford free access to the basal structures of the tumor and an easy approach to the vessels and routes of extension along the lymphatics. See diagram (1)

There will be a large number of accessible growths which will be amenable to implantation without surgical exposure, but there will also be many inaccessible neoplasms which must be exposed surgically for a proper implantation. Again, there will not be many deep seated lesions which lie too far distant from the orificial openings to be within range of the palpating finger that is to be applied to the external surface. *In any case where surgical exposure makes the neoplasms more accessible, the implantation with bare tubes is more accurately performed.*

The second step consists in the ligation of the main arterial supply to the tumor with disregard of the collateral branches, yet, at the same time these vessels subjected to ligation are dissected up to near the innermost portion of the tumor. But traumatization of the cancer tissue is not to be tolerated. Where an involved organ or area has a definite blood supply, I deem it absolutely essential to ligate the arterial supply partially or almost completely if possible to do so without producing gangrene or necrosis. The more commonly involved organs fortunately are supplied by several main arterial branches which may be ligated because the collateral circulation and capillary anastomosis is such that gangrene is not to be feared. In some instances it will be inadvisable to ligate all the main arteries to obviate necrosis. The particular lesion will call for either a complete ligation if possible or only a partial ligation of the supplying arteries and in others, ligation will not be tolerated. The uterus represents one of the first class, the tongue, the second, and bladder that of the latter.

Should it be necessary to dissect out the arteries which lie in a field removed from the line of incision such as happens after laparotomy in carcinoma of the cervix, then the arterial supply should be partially ligated as far away from the diseased tissue as practical.

The ligation of the main arterial branches supplying the tumor is too often omitted entirely. In some cases it is delayed until after the elapse of valuable time, as a result of waiting, the radiation produces a slough with severe hemorrhage. In some cases, it is deferred because of waiting for the opportunity to develop of treating metastatic lymphatic glands. *I believe, since this operation will become imperative, in such a high number of cases, that it should be performed as a primary early procedure before the patient becomes weakened from the loss of blood. It can not be refuted that the arrest of nourishment to the neoplasm does not render the cancer cells more susceptible to the radiation.*

Palpation is the only means of determining the degree and particular features of the extensions of the neoplasm (in most instances). The sense of touch, which may be developed to a high degree of accuracy will enable the surgeon to outline those structures which are invaded by the

No 2—Proper method of implanting tumor through surgical exposure.

amount of induration present. The attempt to palpate a lesion by placing the fingers on one side only, or with the other hand on the opposite side which is covered with skin, muscle and other tissue, will usually only give a vague and indefinite perception. But where one is permitted to place the fingers of one hand on the outer surface and those of the other hand on the inner or basal portion of the involved area, with these covering tissues removed, the extensions are mapped out clearly and concisely, not to overlook the amount of movability present. (Again see diagram 1) Surgical exposure, then, of the involvement by the basal route becomes a necessity on many occasions if bimanual palpation is to be accomplished. Lesions of the tongue or floor of the mouth, carcinoma of the cervix, high rectal growths are often so exposed by the writer that this advantage may be gained.

The fourth step of implanting the tumor, after a determination of the area of involvement, is undertaken by inserting an implant needle into the basal structures and passing it through the body of the tumor until the point is felt to approach the palpating finger held on the opposite side. See Diagram, II. The important structures, i. e., the arteries, veins and nerves with neighboring organs lying in view, obviates any injury of these on the insertion of the implant needles. The left hand not only palpates the indurations which necessarily are more heavily embedded, but is used to hold the mass firmly which permits the needles to be passed accurately and with precision at regular distances apart.

And since the operator is aware of the approach of the needle point by the sense of touch, before the penetration of some 2 to 5 mm in most cases, the introduction of the implant needle is halted before entering the ulcerated surface, which prevents withdrawal of infection into the deeper tissues and operative wound. The needle is withdrawn for a short distance and the plunger is forced forward leaving the bare tube deposited in the channel, after which, the needle is again withdrawn for a short distance of about $\frac{3}{4}$ to 1 cm for the deposit of another seed. (I commonly prefer to embed seeds every $\frac{3}{4}$ cm in carcinoma tissue) The withdrawal of the needle and the depositing of the seeds at these equidistant positions is repeated until the last seed is left in situ near the point of insertion. My practice is to implant sections of the cancerous field individually by inserting a sufficient number of needles, more or less parallel and withdrawing one needle at a time, implanting each channel as described above. After this, other sections are likewise mapped out and implanted. The area of tissue circumscribing the growth for some distance is implanted with bare tubes of lower units than the ones used intratumorally, besides, the distances apart are increased as the circumference of the area to be implanted is approached. Thus, in the treatment of many tumors and especially those of moderate size, I am using only two strengths of

No 3—Proper distribution of radium seeds in and circumscribing tumor

seeds—those of higher denomination for the intratumoral mass and the lesser fraction for the surrounding tissue.

But for those growths in the advanced stage with extensive ramifications in which, besides the main mass, the regional nodes are known to be involved and there is little doubt that there are minute detachments of cell masses beyond which

are not palpable, I have recently used three denominations of seeds. Those of the lowest units added for the treatment of the very outermost areas. The radiation of which seeds devitalizes the cell detachments and early involved regional nodes. This use of different strengths of seeds will enable one to use large quantities of emanation distributed over a wide field without danger of slough formation. See Figure III for a schematic diagram of a properly implanted neoplastic field. Recently I have used over 4,500 mc hr of unfiltered emanation in a single tumor field within the lower abdomen without disagreeable results. This emanation is unfiltered, therefore the effects from the beta and gamma rays are considerable. And the gamma radiation alone is even a larger quantity than that usually advocated by many at the present time for application to the lesions of the surface or within the body cavities enclosed in metal containers which are of sufficient thickness to remove all the beta and to lessen the intensity of the gamma rays.

The factor of dosage or quantity of irradiation which may be applied or implanted is necessarily a variable one even for lesions of the same type. It is needless to add that we must consider the dosage in conjunction with ligation more seriously than when radium is implanted alone. The ideal goal is to produce as complete an avascular field as possible and at the same time to step the quantity of radiation up to the limit of tolerance without producing an annoying or serious necrosis. The quantity of emanation which may be deposited into a neoplastic area is surprising if the radium tubes are distributed widely and at regular distances. Since this is a new field of endeavor, the clinical experience of the operator and the knowledge of the physics of radium must be the guides of the dosage to be employed. The proper distribution of radium bare tubes into a neoplasm depends upon the exact determination of the extensions. As seen in the diagrams, the attempt to blindly implant such will too often be followed by failure.

To accomplish the distribution of the seeds regularly and equidistant apart, some special type of needle must be used which will permit at least 5 or 6 or more seeds being deposited in one puncture channel. The implantation of 80 or 90 bare tubes often used would necessitate a great deal of injury and unnecessary trauma with a more likely chance of metastasis should we introduce each bare tube through an individual needle. These tubes would be deposited with irregularity and awkwardness. In the instance that several or more seeds are "bunched," the total irradiation in the limited area will in many instances cause necrosis from the overdose. While in other sections no seeds at all will be deposited or else will be too scattered to lethally affect the cancer cells. For the above mentioned reasons, it is a fault to attempt the implantation of lesions

without the use of a special needle in which the seeds may be reloaded and discharged until the desired number is deposited into each puncture channel. To meet this necessity, I have recently invented a new reloading cartridge needle.

Before the combined procedures mentioned above are resorted to, I am opposed to the application of external radiation because the exces-

No 4—Improper implantation of tumor through external surface

No 5—Improper implantation of tumor

sive radiation received by the skin from the seeds deposited below added to this surface radiation is very apt to destroy the skin. Again, any radiation applied to the surface of the primary lesion or deposited into it, will not only produce an inflammatory induration with the formation of fibrosis, which is difficult to diagnose from carcinomatous infiltration, but will be most confusing in determining and distributing the proper number of seeds. Should this last factor be all considered, either the excessive dose will produce a slough or a deficient dosage will fail to check the growth. To sum up, the most favorable type of growth for the application of the principles outlined above is the virgin growth which has not had previous treatment.

To go further in the discussion of the disadvantages of implantation through the external surface of growths which have reached a stage of appreciable advancement, they are in most cases ulcerated and infected.

The insertion of the radium needles from without through this infected surface is often followed by a severe and painful inflammation due to the introduction of bacteria into the deeper tissues, which often produces a slough with resulting sequelae. This sequelae may take the form of hemorrhage, fistula, perforation of the wall of an organ or bone necrosis with the production of severe pain and discomfort. Another item not to be overlooked is the hemorrhage into the tissues from the puncture needle being inserted into a vascular field whose blood supply has not been diminished. But this unwarranted consequence is avoided when the needles are inserted through the aseptic base of the wound (of the surgical exposure) which leaves the reaction comparatively mild.

Diagram No. 5 will not take much explanation to make plain how, even with the most ideal destruction of the body of the tumor by a most precise intratumoral injection of seeds through the external route, remnants are often left at the peripheral area, in the adjacent tissues neighboring the tumor or in the regional lymphatics. These detachments will give rise to the recurrence, even though the gamma radiation which is fanning out in all directions is considerable. The quantity of radiation necessary to arrest their development is not excessive if properly distributed in the initial or early stage of growth. Except in selected cases, the difficulty of depositing seeds into this indefinite and inaccessible field is too great to warrant the attempt. (See Diagrams 4 and 5.) The safest procedure to follow in suitable cases is that of surgical exposure of the tumor base with the distribution of bare tubes not only in the tumor but widely into the adjacent tissues circumscribing the growth. A further argument for this latter method of implantation is a study of the statistics of surgical eradication which clearly shows that the highest number of cures is obtained by that surgeon, who, trained by years of experience and possessing natural ability, has made the utmost effort to dissect out the growth with adjacent tissues just within the range of possibility. Those who are acquainted with the concepts of implantation do not doubt that the radiologist is capable of depositing seeds not only to that limit of the surgeons line of excision of the tissues but even beyond. The knowledge of the effects produced by the irradiation emitted by the bare tubes when properly distributed leaves no doubt concerning the advantage gained.

In some cases the incision may be extended along the line of the vessels for exploration should there be apparent glandular involvement.

As an example in the neck since the lymphatics accompany the blood vessels. Any freely movable gland which separates from its bed may be dissected out but when attempting to dissect a metastatic mass, and it is found to be definitely fixed to other structures, I believe it is better to implant with bare tubes with the idea of returning later for resection and implantation in the bed of removal, if necessary.

All the above procedures will be able to be accomplished with one exposure, with a few exceptions, in those types of cases applicable to this method of treatment.

In a wide review of the literature, these facts are evident. Surgical exposure for implantation is on a sound basis, ligation has not been stressed sufficiently in combination with implantation. Much has been said of resection or partial removal of growths followed by implantation or other forms of radiation, but there has been a failure to appreciate the advantages offered by surgical exposure to (a) partially ligate the arterial supply, (b) bimanually palpate the extent of the indurations between the opposing fingers (c) implant the growth and basal structures through the wound of approach, (d) treat the metastasis through the same incision.

REPORT OF TYPICAL CASE

Report of a case applicable to the four cardinal principles described above. Mrs. M. H., referred by Dr. T. H. Morgan, was admitted to Polyclinic Hospital January 27, 1925, complaining of excessive uterine bleeding, general weakness, and loss of weight.

Marital relations, menses have always been regular but profuse. Yet the last regular period is unknown. She has three children, fourteen, seven and six years of age.

Vaginal examination revealed a large cauliflower, fungating, ulcerated mass involving the cervix and filling a great part of the vagina with extensions in to both parametria.

Operation briefly stated, included a lower mid-line incision with ligation of both ovarian arteries, and the anterior branch of the internal iliac on the right side and the uterine artery on the left. After the growth was palpated between the index finger of the left hand in the vagina and those of the right hand in the abdomen to determine the limits of extension, 68 bare tubes were deposited into the neoplasm under guidance of the eye at the same time using the finger of the left hand below to act as a guide to the needle.

The patient suffered no more than the usual abdominal operative case, being up and around in some ten or twelve days. The discharge and foul odor ceased in a very short time. She has had no bleeding since operation and has been free of bladder or rectal disturbances. She gained fifteen pounds in six weeks after operation and has been doing her housework ever since. At the

present time she has no signs or symptoms of persistence of the growth

SUMMARY

Surgical exposure (1) is the only means of transforming an inaccessible neoplasm into an accessible one, (2) affords an opportunity to bimanually palpate the lesion, in the majority of deep seated neoplasms, to determine the character of the extensions, which is essential if the implant needles are to be inserted into all parts of the tumor, (3) obviates injury to the large arteries, veins, nerves and other important structures since they are exposed to view, (4) becomes the route for ligation of those vessels feeding the growth, if this latter step is practical

Ligation of the main arterial supply (a) renders the malignant cells more susceptible to the radium rays, (b) acts as a safe guard to control hemorrhage, either resulting from the erosion of a vessel by the invasion of the growth or radiation necrosis, (c) leaves the field of implantation dry, thus removing the annoyance from hemorrhage which prevents a successful distribution of seeds, (d) when performed early, does not permit the loss of blood, thus debilitating the patient to the point of having to divert the treatment from the aggressive to the palliative form, (e) greatly reduces the hemorrhage into the tissues caused by the puncture of the implant needles, which, besides interfering with the action of the radiation, favors infection, necrosis and severe pain, (f) arrests metastasis

Bimanual palpation of the tumor region (i.e., between the fingers of one hand placed on the external or outer surface and those of the other hand within the wound on the inner or basal structures of the growth) (1) renders most valuable aid in estimating the irregular areas of extension into the circumscribing tissues and regional lymphatics, (2) if substituted by palpating the external surface alone, renders it impossible in many cases to acquire the above facts or makes this determination less accurate

Implantation via the peripheral or basal route is to be preferred over other methods because (1) it is the only method in the treatment of deep seated inaccessible neoplasms of depositing bare tubes with precision into the peripheral growing cell areas and into the circumscribing tissues which harbor the cell detachments and early involved regional lymphatics, (2) attempts to blindly implant these inaccessible lesions through the external surface results in the neglect of the distribution of bare tubes into the areas of invasion (mentioned in No 1 above) with the result that the growth persists or recurs, (3) the

fingers placed on the outer surface of the tumor not only are used to hold it firmly but to guide and direct these implant needles which are inserted by sight accurately into the different sections of the tumor with the result that there is little error of irregular distribution of the bare tubes

CONCLUSIONS

(1) Surgical exposure of the basal structures of a great many cases of inaccessible neoplasms should be instituted in order that (a) bimanual palpation may be used to determine the limits of extension which is essential for, (b) an accurate and even distribution of bare tubes into the growth

(2) Since partial ligation of the arterial supply will become imperative in such a high number of cases and is per se a therapeutic measure, it should be performed primarily as an adjunct to implantation in suitable cases

(3) Opportunity to explore or treat metastatic glands is often afforded by merely lengthening the incision

(4) The growth is not disturbed, therefore the chances of metastasis are not increased

(5) All the above described procedures, i.e. surgical exposure, partial arterial ligation, bimanual palpation and the basal method of implantation are accomplished at one sitting and frequently under local anaesthesia

(6) The extent to which the above principles may be applied to any particular lesion will depend upon the ingenuity of the operator and the anatomical features of the structures involved

(7) Such types of lesions as carcinoma of the tongue, tonsil, floor of the mouth, cervix and high rectal growths will in the majority of instances, because of their unique anatomical state, in which implantation or the insertion of radium needles is indicated, conform to the use of the associated principles described above as the treatment of choice

THE STOFFEL OPERATION FOR SPASTIC PARALYSIS*

By PRESCOTT LEBRETON, M.D. and ROBERT M. CLEARY, M.D.,

BUFFALO, N. Y.

As the Stoffel operation has not as yet found its place, so that the indications and the results are definitely determined, reports from different clinics, tabulating varied experiences, are of value. The object in the Stoffel operation is to cut down on one or more of the motor nerves of arm or leg, to isolate the motor branches to some of the overacting muscles causing interference with function, and to cut these nerve branches so that there will be a partial permanent paralysis. This gives, in the end, a better muscle balance, and lessens the spasticity, and tendency to deformity.

During the past few years the writers have operated on seventeen cases of spastic paralysis. Nine of these were boys and eight were girls. Five were hemiplegias and the remainder mostly paraplegias. In eight cases the internal popliteal was attacked, in five the obturator, in three the median, and in one the sciatic nerve. There were no infections. One boy died soon after operation, the cause of death being acute tonsillitis, endocarditis and general septicemia. The autopsy showed clean wounds over the obturator nerves. Excluding this one case, there remained sixteen cases, of which one half or 50% could be classified as good results. Four or 25% showed only fair results. Four or 25% poor results. By poor results is meant a continuance of spastic deformity, so that in these cases a tenotomy was needed later on in addition.

Before operating it is necessary to have at hand a battery to test the nerves. The writers use the common small faradic battery. One electrode is the usual wet sponge, to be applied to the patient's body at some convenient site. The other electrode is a metal applicator, in the handle of which a hole is drilled for the end of the battery wire. With the help of a dry sterile towel, the wire handle of the applicator are grasped firmly and the sterile tip is applied to the bare nerve branch. The muscle innervated will contract forcibly on contact. Too much current causes many adjacent muscles to react, therefore a small current, just enough to irritate the individual nerve, is sufficient. Often a light pinch by forceps will act as well as the current.

TECHNIC OF OPERATION

INTERNAL POPLITEAL NERVE (for heel cord contraction)

Incision is made beginning at the middle of the popliteal space, straight downward three inches. Avoiding the external saphenous vein

and nerve which are superficial, the main trunk is readily found. The branches to the gastrocnemius are first in view and easily separated. If clubfoot is present the nerve to the tibialis posticus is found by following down the main nerve between the muscles and testing by battery. The writers have usually excised one inch of each of the two branches to the gastrocnemius, sometimes adding one half of the branch to the tibialis posticus where there is a clubfoot tendency. Division of the entire branch to the tibialis posticus may cause a flatfoot. Removal of one to one and a half inches of the nerve branch is surer than a simple division. Some prefer to paralyze the soleus instead of the gastrocnemius, to avoid the possibility of the development of backknee. A slight plaster cast with the foot in normal position is applied for three weeks.

OBTURATOR NERVE

(for adductor contraction)

Incision from near the pubic spine along the inner side of the adductor longus. The anterior branches of the nerve are easily found by dividing this muscle and retracting. If the muscle is not divided it is more difficult to find the nerves. Generally three small branches, surrounded by a plexus of veins, lie at the bottom of the wound. In a very severe case, it is best to follow the branches back close to their exit to find and cut the deep motor branches. As a rule section of the superficial branches suffices. A double plaster spica to place the thighs in abduction is applied for a short time.

SCIATIC NERVE

(for flexion of knees)

Incision from the gluteal fold in the midline of the thigh, downwards for four inches. The long head of the biceps muscle is retracted inwards, after which the motor branches to the long head of the biceps, and to the semimembranosus and semitendinosus are found. Usually the branches to the semitendinosus and the short head of the biceps are left untouched.

MEDIAN NERVE

(for pronation of the hand and flexion of the wrist and fingers)

Incision from the inner edge of the biceps tendon down the center of the forearm across the pronator. The nerve is found readily at the bend of the elbow and by cutting the pronator radii teres, the nerve can be traced a good distance. On the anterior aspect are the branches to the pronator, the flexor carpi radialis, and

* Read at a meeting of the Interurban Club, Buffalo, N. Y., October 21st, 1925, with demonstration of cases.

the palmaris longus. Back of the nerve can be found the branch to the flexor sublimis as a rule, and it may be desirable to cut this partially or entirely, leaving the profundus untouched.

The ulnar nerve can be attacked to reach the flexor carpi ulnaris and thumb muscles.

Remarks

Tenotomy is best reserved for cases of real contracture, that is, in cases in which, under an anesthetic, there is found a real shortening which is not spastic. In one case the writers had to divide the pectoralis major and the biceps in the arm for contracture of shoulder and elbow. In some cases Soutter's operation on the hip muscles must be added for hip flexion. The Stoffel operation is supposed to be of no value in diffuse spasm where all the muscles are equally overactive. It can be seen that care must be used in selecting the cases. Also, when the mentality is of low grade, these young patients will not follow up the after treatment by voluntary exercises as they should. These posture exer-

cises are of great value. In adult cases of hemiplegia, the after treatment can be well carried out. As in infantile paralysis, these patients are poor operative risks, and acidosis and other consequences of the anesthetic must be watched for. Gas and oxygen form the best anesthetic by far. In cutting the branches excision of an inch or more is the rule. As these branches are motor only no pain is felt after operation. Pain is due to rough handling of the main trunk which contains sensory fibres.

In conclusion it may be stated that in the opinion of many surgeons the results are best in the obturator cases and least in the median cases. The experience of the writers would bear out this statement. Spastic paralysis is a difficult condition to treat. Forster's section of nerve roots injection of alcohol into nerves and tenotomy, leave much to be desired. In the Stoffel operation we have a new method of weakening the stronger set of contracting muscles and thereby giving the opposing group a better chance to function.

Case	Date of Operation	Initial	Age	Type	Deformity	Nerve	Result
1	1922	E M	6	Hemiplegia	Tight heel cord	Internal popliteal	Good

THE TREATMENT OF SCARLET FEVER

By PERRY A. BLY, M.D.,

ROCHESTER, N. Y.

BEFORE we can institute a rational therapy, we must ask ourselves, "What is Scarlet Fever?" The knowledge that certain strains of Hemolytic Streptococci are the causative factors, and that specific anti-bodies are produced which may be available in the treatment of Scarlet Fever, has transferred our therapy from the realm of the empiric and symptomatic to that of the exact and specific.

Zingher¹ defines Scarlet Fever as "A local disease of the naso-pharyngeal mucus membrane, caused by certain specific strains of the Hemolytic Streptococcus. A soluble toxin is produced locally, which is absorbed into the system of the patient, giving rise to the skin and constitutional symptoms. Further, it may be said to be a combined toxic and bacterial invasion. We can neutralize the toxin, but immunity to the disease is antitoxic and not anti-bacterial. Hence, the protection, conferred by a previous attack of Scarlet Fever, while the individual has no bacterial immunity.

In 1912, Reiss and Jungman² published the results of their investigations on the use of convalescent Scarlet Fever serum. They pointed out the rapid disappearance of the toxæmic symptoms, and recommended its use in severe Scarlet Fever.

In 1915, Zingher advocated the use of whole convalescent blood, and, also, the employment of whole normal blood.³ He recommended convalescent blood in the so-called "toxic" types, and used normal whole blood in the secondary septic complications, largely for its tonic effect.

Following his technique, we began to use citrated convalescent blood in 1915. Our results were most gratifying. In a hospital for contagious diseases, it was comparatively easy to obtain suitable donors. The blood was drawn at the end of the fourth week of illness, and sometimes as late as the eighth or, even tenth week after the beginning of the illness. Of course, a blood Wasserman had been done.

The blood was drawn into syringes of fifty, and one hundred cubic centimeters capacity, in which two per cent of a ten per cent solution of sodium citrate had previously been placed. As

each syringe was filled, it was detached from the needle, and the contents were thoroughly mixed. A platinum needle, about No. 18 gauge was used. The blood was, now, injected directly into the thighs, buttocks, lumbar muscles and triceps. In this way, chance of contamination was reduced to a minimum.

Later, we substituted pooled, blood serum, which was first tested for sterility, preserved with 3% of tricresol, and put up in twenty cubic centimeter portions. The average amount of whole blood injected was 150 cubic centimeters, while twenty cubic centimeters of blood serum constituted the average injection.

Following the injection of blood or serum, the patient usually sleeps for several hours, and awakes, greatly improved. The stuporous child is alert, delirium has disappeared, the pulse is of better quality, and liquids are readily taken. This is more remarkable, when it is remembered that most of these patients have extensive faucial involvement, and that the dysphagia must be most distressing.

Early in 1924, we began the use of Dochez Serum. Birkhaug⁴ in comparing convalescent serum with Dochez serum says that while both sera appear to contain specific antitoxic anti-bodies, which produced definite clinical results, there existed a difference between the effect of the two sera in bringing about a cure. While convalescent serum caused a rapid diminution of the manifestations of the toxæmia, it did not apparently hasten convalescence or affect the duration of the exanthem.

It will be noticed that in all cases there was a rapid decline in temperature and improvement in the general condition. In the use of whole blood, there was usually a temporary rise, followed by a marked decline. In only one case was the injection repeated. Convalescent serum was given four times to one patient. Improvement was noticed after each injection.

Concerning the Schulz-Carlton extinction phenomenon, or so-called "blanching test," Dochez' serum caused a more uniform blanching, and over a larger area. Blanching was obtained with smaller amounts of Dochez' serum than with convalescent serum. Definite blanching was obtained with 1 cc Dochez' serum in four cases.

¹ Read at the Annual Meeting of the Seventh District Branch of the Medical Society of the State of New York, Auburn September 24, 1925.

TABLE I
CONVALESCENT WHOLE BLOOD

Sex	Age	Day of illness	Type	Eruption	Fauces	Temperature Before	Temperature After	Amount given	Remarks
F	26	5	Toxic	Bright scarlet	Congested	104.8	100.4	200 cc	Puerperium, marked improvement in 12 hours
M	5	5	Toxic	Dark purple	Exudate	105	102	150 cc	Very toxic, delirious, Cheyne-Stokes respiration, cervical abscess on 12th day
F	7	2	Toxic	Bright scarlet	Exudate	99.4	next day	200 cc	Recovery
F	37	5	Toxic	Scarlet	Congested	104.6	99.2	200 cc	Very toxic, delirious
F	6	6	Toxic	Dusky red	Congested	101.4	98.6	110 cc	No complications
M	4	9	Toxic	Purple	Exudate	104	102.4	250 cc	Uneventful recovery
M	5	5	Toxic	Bright scarlet	Congested	99.2	next day	110 cc	Condition poor, pulse 140, poor
F	21	4	Very toxic	Bright scarlet	Exudate	102.6	99.6	110 cc	Uneventful recovery
F	8	8	Very toxic	Purple	Exudate	105	99.2	150 cc	Condition very poor, nephritis
F	8	4	Toxic septic	Purple	Exudate	104.2	100.2	250 cc	Death on 12th day
M	2	6	Toxic	Fading Purple	Exudate	105.2	100.2	200 cc	Recovery
M	21	5	Toxic	Purple	Exudate	104.8	100	160 cc	Puerperium, confined 5 days before, delirious, condition poor
						102.6	99	400 cc	eventful recovery
									Moribund on admission, hemolytic streptococcus septicaemia. Died 22 hours after admission.
									Hemolytic streptococcus septicaemia, septic arthritis elbow, hemolytic streptococcus in joint
									Died.
									Uneventful recovery
									Manacal, slept 12 hours after blood, otitis media on 15th day
									Uneventful recovery

TABLE II
CONVALESCENT BLOOD SERUM

Sex	Age	Day of illness	Type	Eruption	Fauces	Temperature Before	Temperature After	Amount given	Remarks
F	5	10	Toxic	Fading	Exudate	102.4	99.2	20 cc	Very toxic. Uneventful recovery
F	9	13	Toxic	Fading	Exudate	101.2	99	10 cc	Uneventful recovery
F	2	12	Toxic	Faded	Non exudate	103.6	98.4	20 cc	Profuse nasal discharge ceased on 4th day
M	22	5	Very toxic	Intense scarlet	Exudate	on 2nd day		20 cc	Recovered.
		7	Very toxic	Intense scarlet	Exudate	105.8	102.6	20 cc	Delirious, pulse poor
		8	Less toxic	Fading	Exudate	103.6	101	20 cc	Quiet after first injection, later delirium.
M	12	4	Less toxic	Faded	Non exudate	102.8	100	20 cc	Slept 6 hours, pulse poor, delirium returned, pulse much better quality
M	9	2	Toxic	Moderate	Clean	101.2	99	20 cc	Uneventful recovery
M	12	5	Moderately toxic	Intense	Clean	104.2	99	20 cc	Wassermann No 4
M	2	10	Septic	Faded	Clean	104.6	99.4	20 cc	Active delirium, albumuria on 12th day
F	46	6	Toxic	Moderate	Clean	on 2nd day		20 cc	Recovery
F	13	5	Moderately toxic	Moderate	Exudate	103	98.4	20 cc	Slight edema of larynx, delirium
						on 2nd day		20 cc	Recovery
						103.6	100	20 cc	Slough on eyelid, hemolyt, strep recovered, later, otitis media and mastoiditis. Recovered.
								20 cc	Otitis media, cellulitis of cheek, hemolytic strep in abscess of cheek
								20 cc	Recovered
								20 cc	Uneventful recovery
								20 cc	Uneventful recovery

TABLE III
DOCHEZ' SERUM

Sex	Age	Day of illness	Type	Eruption	Fauces	Temperature Before	Amount given	Remarks
F	17	2	Moderately toxic	Moderate	Clean	103.4	99.2	Temperature normal 24 hours after
M	18	4	Moderately toxic	Brilliant scarlet	Exudate	104.8	99.4	Otitis media on 9th days
F	21	2	Moderately toxic	Moderate	Exudate	101.4	98.6	Recovery
M	10	2	Mild	Moderate	Exudate	103	98.6	Uneventful recovery
M	6	2	Mild	Moderate	Congested	102.6	99	Uneventful recovery
M	18	3	Moderately toxic	Moderate	Exudate	104.4	99.4	Uneventful recovery
M	10	2	Mild	Moderate	Congested	103.4	99	Uneventful recovery

M	20	4	Moderately toxic	Fading	Exudate	104.2	98.6	Uneventful recovery
F	48	6	Toxic	Brilliant scarlet	Exudate	103	98	Uneventful recovery
M	18	3	Mild	Brilliant scarlet	Exudate	102.8	99	Uneventful recovery
M	23	12	Toxic	Fading	Congested	104.3	101	Treated at home until 12th day, beginning edema of larynx, symmetrical subperiosteal abscesses over tibiae, hemolytic strep, found in both
						98.6	in three days	Recovered

To summarize these lists

12 patients received convalescent whole blood, mortality, 25% Of these, eight were in desperate condition Two of the fatal cases showed Hemolytic Streptococci in the blood culture, while acute nephritis caused the third death

10 patients received convalescent blood serum, all recovered

12 patients received Dochez' Serum All recovered Dochez' Serum appeared to bring about a more rapid improvement in the symptoms of the toxæmia, and particularly, an earlier disappearance of the exanthem

Our non-specific routine treatment is simple, but some of our procedures are difficult to carry out in a private home Every patient is kept in bed at least twenty-one days, counting from the first day of illness In the absence of renal involvement, the drinking of generous amounts of water is urged We cannot force water through an impermeable kidney, and I cannot see the wisdom of forcing liquid into a patient whose tissues are beginning to be water-logged Nephritis has been our least frequent complication

However, we do believe in frequent washing out of the lower bowel with normal saline solution When the angina is severe, the necessary amount of water may be introduced in this way

Believing that attention to the throat and naso-pharynx decreases the incidence of middle ear involvement, we very gently flush out the naso-pharynx, and then the fauces are painted with a 20 per cent solution of Argyrol All this is done six or eight times in the twenty-four hours

In 1,133 cases of Scarlet Fever, treated at the Rochester Municipal Hospital, Otitis Media occurred in 7.95% Frequent examination of the ears is made, and a tympanum which is only moderately bulging, is promptly incised The treatment of a discharging ear consists in keeping it as dry as possible This means a great deal of time and labor, but, it pays A moderate rise in temperature, after the initial fever has subsided, is a warning to look at the ears, even though the patient does not complain of pain or tinnitus

Nephritis was a complication in 1.63% of cases A small number I believe the routine twenty-one days in bed, the abundant amount of water, and restriction of the diet to semi-solids during the febrile period, furnish the reason

A rather painful complication is arthritis This is relatively common The smaller joints are most frequently attacked, and it is usually symmetrical The temperature rises to 102 or 103 degrees, and the patient complains of pain in the joint The joint is immobilized, and the pain and fever rarely last more than a few days

In only two cases, did suppuration occur. In both cases the Hemolytic Streptococcus was found in the joint, and both terminated fatally.

Two deaths were caused by a Hemolytic Streptococcus meningitis. Edema of the larynx is a rare, but serious complication. Three of our cases required intubation, and all recovered.

In the absence of complications, our patients are discharged on the thirtieth day. Why the thirtieth, and not the twenty-ninth, or the fifty-ninth? If we accept, as we surely do, the Hemolytic Streptococcus, or rather, several specific strains thereof, as the cause of Scarlet Fever, can we not prophesy that the discharge of the patient will depend upon negative cultures, made from the nose, ears, throat and naso-pharynx?

And what about the nephritides of early adult

life? I believe that the foundations for some of these were laid at the time of an early, perhaps forgotten, perhaps unrecognized Scarlet Fever.

INFLUENZA AND MEASLES, THEIR EPIDEMIOLOGIC SIMILARITY

By EDWARD S GODFREY, Jr, M D,

Director Division of Communicable Diseases New York State Department of Health

NINETEEN HUNDRED AND TWENTY-SIX will be a "measles year" in New York State unless the record of twenty-two years is to be broken. Not since 1903 have there been three successive years of declining mortality from measles, so that the fact that the rate in 1924 was lower than in 1923, and that it was lower in 1925 than 1924, make it almost certain that 1926 will see a considerable increase. If the number of deaths from this cause is to be kept below 300, a good deal more intelligent effort will have to be given to the problem than has been the custom during "measles years" of the past.

From the administrative standpoint measles epidemics should be regarded as influenza epidemics in miniature. While there are differences in the symptoms of the two diseases and even to some extent in the character of the epidemics themselves, yet the latter present sufficient points of similarity to warrant the above statement. It is customary to learn how to handle a big job by first learning how to handle little ones with more or less facility. Health authorities therefore should be making use of the measles epidemics that come their way to devise ways and means of minimizing their effects and to obtain practice in mobilizing available resources for emergencies.

Epidemics of measles resemble influenza epidemics in several ways, and the differences, aside from the inherent characteristics of the diseases themselves, are largely due to the difference in the intervals between the epidemics. Widespread epidemics or pandemics of influenza usually appear about once in a generation. Measles epidemics occur in large cities about every two or three years, in smaller places at somewhat longer intervals.

If measles epidemics appeared only at intervals of twenty or thirty years, we would observe much the same disruption of social and economic life that is common to epidemics of influenza, since practically everybody who has not had measles is susceptible to it, and under such circumstances it would not be a disease confined mainly to childhood as it is today, but would attack adults, particularly young adults as well. This has been proven time and again by the occurrence of measles epidemics in isolated communities where the disease has been introduced for the first time or after a long interval.

We have but to read Panum's account of the epidemic of 1846 on the Faroe Islands, where for sixty-five years there had not been a case of the disease. Six thousand out of the 7,800 people in these islands contracted the disease in the space of a few months. The person who had had measles sixty-five years or more previously escaped, while old persons, even of seventy and eighty years, who had never had measles contracted it as readily as the child of seven. In one small village, 80 per cent of the inhabitants were sick at the same time.

Unfortunately, we know nothing of the mortality in this epidemic, since Panum fails altogether to mention it. That none of these cases died is incredible. That only a small number died is improbable, since we are told that the disease was greatly dreaded by the inhabitants. There is no doubt about the mortality in the Fiji Islands epidemic, however, since here nearly a fourth of the population died from measles in a period of four and a half months. Even the "black death" of the fourteenth century is hard pressed by this record. Did they die because of "inherent lack of resistance"? Because their forebears had never had the disease and

they did not inherit an ability to withstand its effects? It is pure assumption to answer these questions in the affirmative in view of the testimony of the physician who tried to look after them. He says it was because so many were taken sick at one time that they couldn't be cared for, couldn't even be fed, so that in addition to the indiscretions which resulted from the lack of medical and nursing care, actual starvation helped bring about this frightful mortality.

In epidemics of both diseases in the average civilized community, while many people are attacked, comparatively few of those attacked die. The actual fatality rate is probably not more than one out of every two hundred. On the other hand, so many are attacked that the gross number of deaths from either disease during an epidemic may exceed the deaths from all other communicable diseases combined, and in the case of influenza may exceed those from all other causes.

Neither disease is apt to kill directly, but both stand preeminent in preparing the way for pneumonia and other complications which are very apt to result fatally. Both are more or less discriminating in whom they kill. They usually select those at the extremes of life—the very young and the old, and those in between who are physically unfit. That the influenza epidemic of 1918 killed more in the "prime of life" and more males than females does not alter this general statement. Men and women in the prime of life can become temporarily "unfit" by undue fatigue, by trying to "see it through" and not "give up" when the attack comes on.

In both diseases the epidemics are commonly explosive, that is, a great many people are attacked within a comparatively short space of time. After a week or two, or perhaps more, of a gradual increase in the number of cases reported, there is a sudden flare-up and the number of cases each week may be double the number for the previous week. This may continue for two or three weeks, when the *rate* of ascent begins to slow down, followed by a period of slight rises and falls and then by a decline, which, however, is never as rapid as the rise. This characteristic explosiveness is due to the presence of two factors: first, the disease itself, second, a large percentage of susceptibles in the community. At the beginning of the epidemic the ratio of cases, the sources of infection, to susceptibles is low and every case is likely to start two or three more and on the average probably does. During the height of the outbreak each case comes in contact with so many immunes that if it were not for the large number of sources of infection at that stage the epidemic would shortly stop. As it is a point is soon reached where, despite the numerous sources of infection, the immunes are so numerous that it takes two cases on the average to find one susceptible, and then the daily

or weekly increase in cases stops and a temporary equilibrium is established. At a point further on the epidemic begins to decline and ultimately reaches a point where it either stops altogether or continues at its "normal" or usual rate for that community.

Epidemics of influenza are commonly more explosive than measles—that is, they rise more suddenly, more persons are attacked per diem, and they fall more rapidly than measles epidemics do. This may be due entirely to the greater concentration of susceptibles to influenza, although the longer incubation period of measles may have something to do with it. This greater concentration of susceptibles for influenza is due, as already stated, simply to the less frequent recurrence of influenza epidemics. One attack of measles nearly always protects against a future attack, and this may be true, to some extent at least, of influenza. However, as measles epidemics recur at short intervals, nine out of ten adults living in the more densely populated states are immune to measles, whereas no such proportion of them are immune to influenza, except possibly during the first few years after an epidemic.

By reason of the explosiveness of influenza epidemics and also because a large number of adults are attacked, there is disruption of business and social affairs and an appreciation of the need of unusual activity by the health authorities. Although there is little that they can do to stop the epidemic, there is no hesitation about providing funds and volunteer assistance is to be had in abundance. The calamitous nature of the event is apparent, the need for relief is recognized, and everybody is glad to help.

Not so with measles. Here is no horrid demon such as we have never seen before, but a familiar pest who shows up every few years to disrupt the routine of the home and school, and here and there pilfer the life of a child—usually one not yet three years old. Does the health officer ask for more nurses, more doctors, more money? He would be laughed at if he did. Does he close up his children's clinics, slow down on his inspections, withdraw his staff from all but the absolutely necessary work that *must* be done, and set them to work at preventing deaths from measles? He wouldn't dare. The fact that more lives may be lost from measles in one month than his child welfare clinic can save in six is not realized by his public. They would probably be severely shocked by anyone of such proposals, and on the other hand remain perfectly contented if he gets up a reasonable number of placards and leaves the result with the Lord.

This ought to be changed. Aside from the direct benefit to be gained by preventing measles deaths as the result of prompt, adequate investigation, there are collateral benefits which make it well worth while. Measles is the typical

epidemic disease spread by human contact, and as such is or should be a valuable basis for comparison for all other diseases—those suspected of being spread in the same way and those suspected of being spread in different ways—whooping cough, poliomyelitis or dysentery. But up to this very moment no one knows precisely what its behavior is in communal life, because all of our data are based on samples. There never yet has been an epidemic where every case was reported to the health authorities, and there will not be until every one knows that if it isn't reported it will be found out anyway with the possibility of a fine in the bargain. Consequently, when we say that fifteen per cent of the cases occur under three years of age, we really only mean fifteen per cent of the sample. When we say that out of every twelve children who contract measles before they are a year old one dies, we mean one out of twelve of the sample. If we say it is more fatal in the city than in the country, more fatal in the country than in the village, we are only talking about samples, and the samples are probably not equally good.

It takes a lot of work by a lot of people to keep up with a measles epidemic during the few weeks it is at its height. Finding the cases that need a doctor, the ones that should go to the hospital, the babies that have been exposed and that should be given serum or some of their

fathers' blood to protect them, the collection of facts, the relief of the overtaxed mother penned up with her brood in a few small rooms, providing nursing care—all of those things should go into the management of a measles epidemic just as much as an influenza epidemic.

Furthermore, it is good practice. Because of the long intervals which separate influenza epidemics, such epidemic has to be dealt with by persons who have grown up since the last outbreak and are therefore lacking in the actual experience which was then gained by those participating in it. There is the same lost motion, there are the same mistakes, the same overwork and underwork that characterized the management the last time. No one knows his place in line, the commanding officer is new to this kind of a job. Instead of an orderly advance, a cheering mob rushes forward to get in its own way as well as the enemy's.

Nineteen hundred and twenty-six will be a "measles year" in New York State. The advance has already shown itself in Beacon, Plattsburg, Oswego and Yonkers. In the latter city, over 2,000 cases of measles were reported during the closing months of 1925, and the toll of deaths from this cause has thus far amounted to forty—all but two of them *under three years of age*.

DEATHS

BOGART, JOSEPH H., Roslyn, Bellevue Medical College, 1872, Fellow American Medical Association, Member State Society. Died February 3, 1926.

CLASS, FRANKLIN MORRIS, New York City, College of Physicians and Surgeons of New York, 1907, Member State Society, Chief Tuberculosis Clinic and Attending Physician Day Camp Vanderbilt Clinic. Died February 12, 1926.

FISCHER, HENRY ARCHBOLD, Jamaica, College of Physicians and Surgeons of New York, 1906, Member State Society, Otologist St. Mary's Hospital, Jamaica. Died January 27, 1926.

GAY, FREDERICK CLIFFORD, Brooklyn, New York University, 1891, Member State Society. Died February 4, 1926.

GIFFORD, WILLIS B., Attica, University of Buffalo, 1876, Member State Society. Died February 13, 1926.

HARRIS, JOSEPH FRIEND, New York City, Albany Medical College, 1906, Fellow American Medical Association, Member State Society, Associate Physician Mt. Sinai Hospital. Died January 31, 1926.

MARINO, FRANCESCO, Brooklyn, Naples, 1905, Member State Society. Died January 8, 1926.

PEELE, GRACE DARLING, Brooklyn, University of Michigan, 1907, Fellow American Medical Association, Member State Society, Brooklyn Pediatric Society. Died February 4, 1926.

SABIN, WILLIAM B., Watervliet, Albany Medical College, 1882, Fellow American Medical Association, Member State Society. Died February, 1926.

WENDE, GROVER WILLIAM, Buffalo, University of Buffalo, 1889, Fellow American Medical Association, American Dermatological Association, Member State Society, Dermatologist General, Memorial, and City Hospitals, Consulting Dermatologist Millard Fillmore Hospital. Died February 9, 1926.

WHEELLOCK, WILLIAM E., New York City, College of Physicians and Surgeons of New York, 1876, Member State Society. Died February 3, 1926.

WOOD, T. CLEMENT, Haverstraw, New York University, 1879, Member State Society. Died January, 1926.

ANNUAL REGISTRATION

Life in New York State and all other civilized communities is assuming an increasing complexity, and the limits of one's dependence are those of communications and transportation. The doctor is deeply affected by this complexity. A hundred years ago the influence of the physicians was confined to the community within the little radius which he could cover with a horse. He practiced within that radius, and he drew all his supplies from that restricted territory. He met few strangers, and knew everybody in it just as they knew him. Matters of registration and identification bothered neither him nor his families.

All this is changed by modern conditions of

living. First, the railroad enlarged the doctor's circle of contact with people, and then the telephone and finally the automobile stretched the radius of his practice to ten fold its former distance until he could not know more than 10 per cent of the people in his community. If he lived in a city, he probably knew less than one per cent of the people within walking distance of his office. There was no ready means of identifying him or of ascertaining his qualifications to practice, and so there arose a necessity for his public registration and identification.

All doctors agree that an authoritative list of medical practitioners is a necessity, and that such a list is not available at present. The sixteen

epidemic disease spread by human contact, and as such is or should be a valuable basis for comparison for all other diseases—those suspected of being spread in the same way and those suspected of being spread in different ways—whooping cough, poliomyelitis or dysentery. But up to this very moment no one knows precisely what its behavior is in communal life, because all of our data are based on samples. There never yet has been an epidemic where every case was reported to the health authorities, and there will not be until every one knows that if it isn't reported it will be found out anyway with the possibility of a fine in the bargain. Consequently, when we say that fifteen per cent of the cases occur under three years of age, we really only mean fifteen per cent of the sample. When we say that out of every twelve children who contract measles before they are a year old one dies, we mean one out of twelve of the sample. If we say it is more fatal in the city than in the country, more fatal in the country than in the village, we are only talking about samples, and the samples are probably not equally good.

It takes a lot of work by a lot of people to keep up with a measles epidemic during the few weeks it is at its height. Finding the cases that need a doctor, the ones that should go to the hospital, the babies that have been exposed and that should be given serum or some of their

fathers' blood to protect them, the collection of facts, the relief of the overtaxed mother penned up with her brood in a few small rooms, providing nursing care—all of those things should go into the management of a measles epidemic just as much as an influenza epidemic.

Furthermore, it is good practice. Because of the long intervals which separate influenza epidemics, such epidemic has to be dealt with by persons who have grown up since the last outbreak and are therefore lacking in the actual experience which was then gained by those participating in it. There is the same lost motion, there are the same mistakes, the same overwork and underwork that characterized the management the last time. No one knows his place in line, the commanding officer is new to this kind of a job. Instead of an orderly advance, a cheering mob rushes forward to get in its own way as well as the enemy's.

Nineteen hundred and twenty-six will be a "measles year" in New York State. The advance has already shown itself in Beacon, Plattsburg, Oswego and Yonkers. In the latter city, over 2,000 cases of measles were *reported* during the closing months of 1925, and the toll of deaths from this cause has thus far amounted to forty—all but two of them *under three years of age*.

DEATHS

BOGART, JOSEPH H., Roslyn, Bellevue Medical College, 1872, Fellow American Medical Association, Member State Society. Died February 3, 1926.

CLASS, FRANKLIN MORRIS, New York City, College of Physicians and Surgeons of New York, 1907, Member State Society, Chief Tuberculosis Clinic and Attending Physician Day Camp Vanderbilt Clinic. Died February 12, 1926.

FISCHER, HENRY ARCHBOLD, Jamaica, College of Physicians and Surgeons of New York, 1906, Member State Society, Otologist St. Mary's Hospital, Jamaica. Died January 27, 1926.

GAY, FREDERICK CLIFFORD, Brooklyn, New York University, 1891, Member State Society. Died February 4, 1926.

GIFFORD, WILLIS B., Attica, University of Buffalo, 1876, Member State Society. Died February 13, 1926.

HARRIS, JOSEPH FRIEND, New York City, Albany Medical College, 1906, Fellow American Medical Association, Member State Society, Associate Physician Mt. Sinai Hospital. Died January 31, 1926.

MARINO, FRANCESCO, Brooklyn, Naples, 1905, Member State Society. Died January 8, 1926.

PEELE, GRACE DARLING, Brooklyn, University of Michigan, 1907, Fellow American Medical Association, Member State Society, Brooklyn Pediatric Society. Died February 4, 1926.

SABIN, WILLIAM B., Watervliet, Albany Medical College, 1882, Fellow American Medical Association, Member State Society. Died February, 1926.

WENDE, GROVER WILLIAM, Buffalo, University of Buffalo, 1889, Fellow American Medical Association, American Dermatological Association, Member State Society, Dermatologist General, Memorial, and City Hospitals, Consulting Dermatologist Millard Fillmore Hospital. Died February 9, 1926.

WHEELOCK, WILLIAM E., New York City, College of Physicians and Surgeons of New York, 1876, Member State Society. Died February 3, 1926.

WOOD, T. CLEMENT, Haverstraw, New York University, 1879, Member State Society. Died January, 1926.

ILLEGAL PRESCRIPTIONS

The physicians of New York State regret that any of their number should be accused of signing blank prescription forms and selling them to druggists to be filled out for the purchase of alcoholic liquors. The daily papers of New York City have printed the names of several physicians and druggists who have been caught in a conspiracy for dispensing intoxicating liquors, and the printed statements are not denied. Physicians are therefore reluctantly compelled to admit a studied violation of the laws by a very few of their number for sordid gain.

Physicians are justly proud of the high standard of their code of ethics. A violation of the confidence reposed in them occurs so seldom that their honesty is presumed and wilful violations of the standards of common behavior are entirely unexpected.

A prescription on file in a drug store is *prima facie* evidence that the physician who wrote it was treating a sick person for whom it was written. It is placed on file by the druggist for his own protection, and is a semi-public document which is open to the inspection of authorized state officials. A prescription for a narcotic or an alcoholic liquor is evidence that the person for whom it is intended is sick, and that the physician who wrote the order is actually treating the patient according to the scientific standards of modern medicine. Giving an alcoholic liquor to be used for any other purpose constitutes perjury and lying, and these are mortal sins according to the standards of the Medical Society of the State of New York.

NAMES FOR NEW CULTS

When a new system of unscientific healing is devised, the most difficult part of the invention is the construction of a trade name which will catch the public ear. A system without a label is no system at all, for the principles of the cultists are all taken from the great reservoir of human credulity, and the main difference between them is in their tags.

The Commissioner of Health of New York City issued a list of the cult systems which were printed in New York City (see this JOURNAL, February 22, 1924, page 230). It contained fifty-five varieties of healing, and was by no means complete at the time it was issued, and is decidedly out of date at the present time, for a new system is born about once a month.

The chiropodists who formerly contented themselves with nails and corns are now seeking to dignify their trade by demanding a license to call themselves "doctors of podiatry." The term "Chiropodist" has become too old fashioned, and so they have coined a new word to give themselves appearance of progress and modernness.

The word "chiropodist" comes from two Greek words—*cheir*, hand, and *pous*, foot. Literally a chiropodist is a hand-footer, and his principle work was to take care of nails on the hands and corns on the feet.

Then came the manicurist—a word from the Latin, *manus*, hand and *cura*, cure—and stole the work of caring for the nails. She did her work openly in barber shops and beauty parlors. Every stage of her work was open to the plain view of the patron and any one else who cared to see, and there was no opportunity to develop mystery in her methods or results. But the corn doctors could still work in secret and could make extravagant claims without detection. They therefore took the half of the word "chi-

ropodist," which the manicurists had forsaken, and called themselves podiatrists, and then because social custom is to conceal the feet, they ascribed to themselves a mysteriousness which is the essential basis of every new system of healing. Podiatrists are manicurists of the feet, and if they are granted the title of "doctor," we may also expect in a short time to have to address every barbershop manicurist as "Miss Doctor."

The makers of braces and trusses have gradually arrogated to themselves the title of "orthopedists," under the mistaken notion that the word means straight feet. The first half of the word, *orthos*, is Greek, and means straight. The second half is not the Latin root, *ped*, meaning foot, but is the Greek root, *paid*, meaning child. An orthopedist is one who straightens the bodies and limbs of children, and until recently the word was written "orthopaedist" in order to indicate its origin from *paid*, child.

The brace makers were too dependent on the medical profession to run the risk of their ill will by assuming the title of orthopedists, and so they looked around for another descriptive term and found it in the word "bandagist," which they claim is much used in Europe. It would seem that a strong objection to the word is that it is commonplace, but evidently the brace makers think they can invest it with sufficient mysteriousness to make it a profitable trademark.

Oralogy is a new system that has ostensibly sprung up within the ranks of the medical and dental professions, and has reached the lusty stage of being the subject of proposed special legislation. Senate Bill Introductory 782 is designed to recognize a group called "oralogists." The word "oralogy" is probably derived from the Latin root *or*, meaning mouth, as in the expression "oral surgery." But the bill says nothing

thousand doctors of New York State constitute an enrolled army whose members are scattered throughout the State. Most of them maintain offices, and are on active duty. Some retain a degree of interest in medical affairs, but are attached to organizations of a commercial, financial, or social nature, and some who were formerly active are conducting private businesses, or are entirely retired from practice.

How shall the State obtain a list of the doctors who are practicing medicine within the meaning of the law? There are two methods.

First, the State may send out its inspectors who shall canvas every street, make inquiries regarding every doctor's sign that they see, look through every telephone book, and obtain a list as complete as possible. Such a list will never be complete, and no court would accept it as final evidence as to those whose names it does not carry.

The second method of obtaining a list of those who are qualified to practice medicine is to require every physician to register his name, address, and qualifications. The physician must do that once under the present law, and must pay a large fee for such registration. The proposed Practice of Medicine Law would require him to

make an annual declaration of his address and intention to continue to practice medicine. Those who do not care to continue to practice medicine will not register, and the lists will be up-to-date and will contain only "live" names.

It is entirely right and sensible that the State should require every person to whom it grants a special privilege should make a formal statement once a year whether or not he wishes that privilege renewed, or wishes to continue to exercise it.

Every man is subjected to several enrollments and these are increasing in number with the increasing complexity of modern life. He must enroll in order to vote, his name is on the local tax lists, and if he is fortunate, he is recorded in Albany and Washington as a substantial contributor to the public income. He enrolls as the proud owner of a Lincoln Junior, or a Packard car, and triumphantly displays his operator's license to the upholder of the majesty of the law at a street corner.

The enrollment of which a doctor should be the most proud is that which lists him with his sixteen thousand colleagues who alone of all the ten million people of New York State, have the privilege and satisfaction of ministering to the sick.

MOVING PICTURES IN MEDICAL TEACHING

It has been the editorial policy of this JOURNAL that every criticism shall include a constructive phase. If a course of action is condemned, a constructive plan should be suggested in its place. Every plan of action that is seriously put forth by conscientious physicians is worthy of respectful consideration, even though its main features are impractical.

Some subjects are so broad and so many sided that any editorial discussion is likely to be incomplete. Such a topic is that concerning the teaching value of moving pictures in the Daily Press Department of this JOURNAL, on page 290 of the March 15th issue. That article should have concluded with an appreciation of moving pictures in medical teaching.

Moving pictures have an essential place in visualizing medical facts. Language is a cumbersome medium for conveying mental pictures of unfamiliar objects. A still photograph is exceedingly valuable, but if the picture is "animated," it gives an instant conception of relations, of speed of motion, of growth, and of other characteristics whose descriptions require long complex sentences. As examples of subjects in which moving pictures are of almost essential value are the following:

The effects of experimental thyroectomy on sheep as done in the Veterinary College of Cornell University are shown in a vivid manner by the use of moving pictures of the flock of sheep

containing both normal and thyroectomized animals.

These pictures have been shown to several groups of medical men, the District Branches of the Medical Society of the State of New York, and in County Societies, and they visualize the weakness and sluggishness of the operated animal.

The peristalsis of the human stomach may be shown by a few moments of animated X-ray pictures more vividly and effectively than by an hour's verbal description.

While a series of X-ray photographs show successive phases of the changing shape of the stomach, the peristalsis becomes vivid only when the successive pictures are connected and animated.

A pathological specimen may be turned about and rotated, and the relation of its parts shown clearly and vividly in an animated photograph.

Many pathological conditions in which the parts may be exposed may be demonstrated and operations shown by the use of moving pictures.

The value of moving pictures in certain phases of medical teaching is recognized by the American Medical Association in providing a large hall in which a succession of pictorial lectures with moving pictures and lantern slides are given throughout every day of the convention.

MEDICAL PROGRESS

The Etiology of Peptic Ulcer—Konjetzny opposes the teaching that peptic ulcer develops on an intact gastric and duodenal mucosa and advocates the view that it invariably forms on a basis of gastritis or duodenitis, which may be focal or diffuse. This inflammation is always most pronounced at the antrum and bulb of the duodenum, or in other words in the realm of the pyloric glands, and while it may often extend into the contiguous area of the fundus it is rarely found in the fundal mucosa apart from this location. In gastric ulcer, further, we usually find the duodenum also inflamed. This inflamed mucosa, gastric and duodenal alike, is the seat of multiple defects, both oval and linear, which are known as erosions and which pass into the ordinary superficial ulcer, all transitions being seen. The author has never seen the slightest evidence of local anemic necrosis or of vascular obstructions under the microscope, which reveals nothing beyond the most typical inflammatory changes, the erosions and ulcers being of purely inflammatory origin. He goes only so far as to state that inflammation is responsible for the superficial ulcer and not for the chronic and indurated formation which requires the presence of another casual factor. In regard to the cause of the gastritis and duodenitis we can only infer that this is an infection, for we know that the microorganisms of typhoid and dysentery can set up ulceration in the alimentary canal. As for the cause of the spread of the ulcer and its chronicity and induration, pathologists and clinicians are practically unanimous that it is the digestive action of the gastric juice, but the author himself seems to be unconvinced although no alternative is mentioned save a possible nervous factor which somehow withdraws protection from the mucosa and allows it to be attacked by the juice.

Bárony takes a view which is exactly opposed to this inflammatory theory of Konjetzny. He adheres positively to the trophic or necrotic theory, which would make of peptic ulcer an analogue of Raynaud's gangrene, varicose ulcer, the ulcers of colitis ulcerosa, and the ulcer of prolapsed uterus. Although the ulcer is a sharply marked off local process this does not mean that there is no underlying general cause. Just as Raynaud's disease may exceptionally attack tissues other than the digits, such as the tips of the nose and ears, so conceivably there might be remote manifestations in peptic ulcer if an exciting cause were forthcoming. In peptic ulcer it is the gastric juice which furnishes a unique factor, but the author is not convinced that

superacidity is a necessary factor and believes that this view is now exploded. In a paper immediately succeeding Bárony's contribution Boas calls attention especially to the superacid theory. It is a mistake, he says, to affirm that the pioneer gastrologists attached overmuch importance to this, and he quotes from Riegel to show that hyperchlorhydria was not regarded as an essential causal factor. To mean anything, the influence of acidity must be studied at the outset, in the stage of erosion and superficial ulcerations and never after the ulcer has become chronic. Thus Kelling studied 150 cases of early ulcer and found superacidity in all but seven. Boas would look with great suspicion on the so-called "anacid ulcer" for it is precisely here that he would expect to find a non-peptic ulcer—tuberculous, luetic, etc.—*Archiv für Verdauungs-krankheiten*, December, 1925.

Histamine Injection Versus the Test Meal in Gastric Diagnosis—In 1922 Carnot, Koskowski, and Libert published the first account of this diagnostic resource and in the present paper Libert makes a later contribution. The histamine injection is especially desirable for the research of the gastric juice. The injection is made into the outer aspect of the thigh, the patient having fasted since the previous evening and having Einhorn's small sound in position in the stomach. A 1-1000 solution of histamine in sterile distilled water is injected in the dose of 1 cm. Although the injection is called harmless it may cause several unpleasant symptoms, notably redness of the face (almost constant) which may extend to the contiguous surface and exceptionally be followed by an eruption, headache, drowsiness, accelerated pulse, and, rarely, vomiting. In ten minutes there will be a hypersecretion of pure gastric juice, the acme of secretion taking place in 30 or 40 minutes. At the desired moment—ten minutes or later—a syringe is attached to the Einhorn sound and the stomach contents withdrawn. A wonderful specimen of gastric juice will be obtained, in the healthy subject at least, clear and of course free from all test meal debris and extraneous fluid. It will be found to be very potent, with a content of HCl of 2 to 2.5 per 1,000. Best of all there is no combined HCl to be estimated. This method ought to supplant the test-meal entirely in certain cases and Carnot, who devised a sham test meal of alcohol, appears to have abandoned it in favor of the histamine method.—*Le Progrès Médical*, January 30, 1926.

about the mouth, but defines orology as follows "A person practices orology within the meaning of this act, who holds himself out as being able to prevent, diagnose, treat, or eliminate disease conditions" The list of subjects of examination ends with "spinal analysis"

A famous Frenchman once said that it was the duty of every educated man to coin three new words every year and add them to the dictionary. He should have been employed to coin new words as advertising trademarks for healers who are seeking special privileges

MEASLES

Measles is a public health problem which deserves the serious consideration of doctors. This JOURNAL, page 312, carries an article on the epidemiological similarity between measles and influenza. Both come in waves, and between the times of their peaks, little is done in preparation for the next wave which is sure to come.

Measles is by no means a "minor" disease. It has caused over 700 deaths annually in New York State during the last five years, and the mortality rate is not diminishing. Whooping cough, another so-called minor disease, also causes about 700 deaths annually, while scarlet fever and typhoid each cause only half that number of deaths, although each is rated as a "major" disease.

Analyzing the deaths from measles, the majority of them are found to occur in children of three years old and under. It is a dangerous disease in young children. The application of this fact is obvious. Protect the young children against infection. While it seems to be true that practically every child in New York State will

get the disease at some time during its life, yet the time of special danger is its early years. The State Department of Health has emphasized this fact again and again, and yet about the same number of children continue to die year after year.

The evident preventive measure is to protect young children from the disease. This is not so commonplace and self-evident as it may seem on first thought. A baby up to three years of age is under control. It does not wander over the streets, but it stays in its own house or yard under its mother's eye and control. It can readily be kept away from other children, and that is the essence of protection. After the age of three, a child is beyond control, but fortunately it is also beyond the danger age for measles.

If physicians advise parents to protect their young children from contact with all persons who have "colds," hundreds of lives will be saved every year. A great responsibility rests on physicians to protect children from measles while they are young.

LOOKING BACKWARD—THIS JOURNAL A QUARTER CENTURY AGO

This Journal for February, 1901, carried the following legislative note:

"No. 205 Senate, Introduced by Mr. Audett. An act to amend the Public Health Law, creating a State Department of Health and the office of Commissioner of Health, and abolishing the State Board of Health."

This law was passed promptly and the State Department of Health was organized along lines which twenty-five years of experience have amply justified. It is interesting to read an expression of fear printed in the April, 1901 issue of the Journal. The anonymous correspondent wrote: "Does our Legislative Committee know that a bill has been enacted destroying the Board of Health? I notice that at the hearing on the measure not a person appeared for or against it. To my mind this was one of the most flagrant instances of destructive legislation in the annals of the Society."

"Twenty years ago after a struggle of fifteen years, the medical profession secured the enactment of a measure creating a State Board of Health. For two decades that board has more or less completely fulfilled its mission though the appointing power has not always had due regard to the fitness of its members for responsible duties."

"By the recent act of the Legislature, instead of nine members who constituted the board there has been substituted a single person who shall have all the powers imposed on the State Board of Health. It is surprising that the framers of the bill concluded to change the name of the nondescript thing they were creating from a Board of Health to a Department of Health. But to the ordinary lawmaker the greatest task would have been to provide a person of such capacity that he could at the same moment, perform all of the duties of the nine select sanitarians of the old board, of all its committees, and even its secretary, in fact who could be a health department in himself. But when they drew the outlines of this extraordinary individual, he proved to be only an ordinary medical graduate."

"At a single stride out the State has passed from the highest to the lowest grade of sanitary organization and service without so much as a protest from a single member of the medical profession."

On this first day of April, 1926, this doleful prophecy is recalled as the State of New York is considering a Practice of Medicine Bill.

MEDICAL PROGRESS

The Etiology of Peptic Ulcer—Konjetzny opposes the teaching that peptic ulcer develops on an intact gastric and duodenal mucosa and advocates the view that it invariably forms on a basis of gastritis or duodenitis, which may be focal or diffuse. This inflammation is always most pronounced at the antrum and bulb of the duodenum, or in other words in the realm of the pyloric glands, and while it may often extend into the contiguous area of the fundus it is rarely found in the fundal mucosa apart from this location. In gastric ulcer, further, we usually find the duodenum also inflamed. This inflamed mucosa, gastric and duodenal alike, is the seat of multiple defects, both oval and linear, which are known as erosions and which pass into the ordinary superficial ulcer, all transitions being seen. The author has never seen the slightest evidence of local anemic necrosis or of vascular obstructions under the microscope, which reveals nothing beyond the most typical inflammatory changes, the erosions and ulcers being of purely inflammatory origin. He goes only so far as to state that inflammation is responsible for the superficial ulcer and not for the chronic and indurated formation which requires the presence of another casual factor. In regard to the cause of the gastritis and duodenitis we can only infer that this is an infection, for we know that the microorganisms of typhoid and dysentery can set up ulceration in the alimentary canal. As for the cause of the spread of the ulcer and its chronicity and induration, pathologists and clinicians are practically unanimous that it is the digestive action of the gastric juice, but the author himself seems to be unconvinced although no alternative is mentioned save a possible nervous factor which somehow withdraws protection from the mucosa and allows it to be attacked by the juice.

Bárony takes a view which is exactly opposed to this inflammatory theory of Konjetzny. He adheres positively to the trophic or necrotic theory, which would make of peptic ulcer an analogue of Raynaud's gangrene, varicose ulcer, the ulcers of colitis ulcerosa, and the ulcer of prolapsed uterus. Although the ulcer is a sharply marked off local process this does not mean that there is no underlying general cause. Just as Raynaud's disease may exceptionally attack tissues other than the digits, such as the tips of the nose and ears, so conceivably there might be remote manifestations in peptic ulcer if an exciting cause were forthcoming. In peptic ulcer it is the gastric juice which furnishes a unique factor, but the author is not convinced that

superacidity is a necessary factor and believes that this view is now exploded. In a paper immediately succeeding Bárony's contribution Boas calls attention especially to the superacid theory. It is a mistake, he says, to affirm that the pioneer gastrologists attached overmuch importance to this, and he quotes from Riegel to show that hyperchlorhydria was not regarded as an essential causal factor. To mean anything, the influence of acidity must be studied at the outset, in the stage of erosion and superficial ulcerations and never after the ulcer has become chronic. Thus Kelling studied 150 cases of early ulcer and found superacidity in all but seven. Boas would look with great suspicion on the so-called "anacid ulcer" for it is precisely here that he would expect to find a non-peptic ulcer—tuberculous, luetic, etc.—*Archiv für Verdauungskrankheiten*, December, 1925.

Histamine Injection Versus the Test Meal in Gastric Diagnosis—In 1922 Carnot, Koskowski, and Libert published the first account of this diagnostic resource and in the present paper Libert makes a later contribution. The histamine injection is especially desirable for the research of the gastric juice. The injection is made into the outer aspect of the thigh, the patient having fasted since the previous evening and having Einhorn's small sound in position in the stomach. A 1-1000 solution of histamine in sterile distilled water is injected in the dose of 1 cm. Although the injection is called harmless it may cause several unpleasant symptoms, notably redness of the face (almost constant) which may extend to the contiguous surface and exceptionally be followed by an eruption, headache, drowsiness, accelerated pulse, and, rarely, vomiting. In ten minutes there will be a hypersecretion of pure gastric juice, the acme of secretion taking place in 30 or 40 minutes. At the desired moment—ten minutes or later—a syringe is attached to the Einhorn sound and the stomach contents withdrawn. A wonderful specimen of gastric juice will be obtained, in the healthy subject at least, clear and of course free from all test meal debris and extraneous fluid. It will be found to be very potent, with a content of HCl of 2 to 25 per 1,000. Best of all there is no combined HCl to be estimated. This method ought to supplant the test-meal entirely in certain cases and Carnot, who devised a sham test meal of alcohol, appears to have abandoned it in favor of the histamine method—*Le Progrès Médical*, January 30, 1926.

The Painful and Latent Phases of Peptic Ulcer—Walko of Prague has made an attempt to fathom the mystery of the latent periods of peptic ulcer by extensive research with röntgenography (*Mittheilungen aus den Grenzgebieten d. Medizin und Chirurgie*, xxxix, 1, 1926). Apparently he has not succeeded, but he has shown that there are no changes either in the direct or indirect rontgen evidence during the transition from active to latent and latent to active phases. He has therefore been forced to the conclusion that the only changes are in the sensibility of the nerves of the vegetative system, although he does not conjecture how the failure to register pain can be brought to pass—whether exhaustion is possible, for example. His summary is in part as follows: The secretory and motor behavior of the stomach shows no evidence of change at any time (indirect signs). Periodicity, alternation of pain and quiescence, is due to alterations neither in the stomach nor in the ulcer itself, and the alternation must therefore be of neurogenic origin. This is not denying that changes do occur in the rontgen signs during the march of the ulcer, but they do not at all harmonize with the changes in painful sensations, save only in such exceptional cases that the agreement can be explained only by coincidence. In fact the changes are often directly opposed to the expectation, for they may be more marked during the quiescent period and less marked in the active period. In other words the cycle of pain has nothing in common with the course of the ulcer. To some extent this is true of all clinical evidence, for we often find little agreement between clinical and r-ray evidence. But this does not mean that the latter is of no value. It is true that we cannot always tell an active ulcer from a scar, but by means of the rays we can show that an apparently healed lesion is only latent.

The Comparative Pathology of Gastric Ulcer—According to Hirsch all of the domestic animals are liable to suffer from gastric ulcer, and especially is it found in the rennet stomach of the young calf although apparently never so long as it is milk fed only. This affection has always been as much of a puzzle to veterinarians as it is to physicians, but a comparative study of human, animal, and experimental ulcer ought certainly to increase our present knowledge. It is evident, for example, that there are separate types of peptic ulcer. The duodenal ulcer may be regarded as one and is extremely rare among the animals. In the stomach the great incidence of ulcer in the so-called "thoroughfare" of the organ—the tract which beginning at the cardia traverses the lesser curvature to reach the pylorus and comprises the first portion of the duodenum—appears to show that thin ulcer has a different etiology or pathology from that of ulcer elsewhere in the organ, and there is reason to

believe further that ulcer on the near side of the pylorus has some special traits. It is often multiple and doubtless has a mechanical casual factor. When the calf passes from milk to coarse, rough fodder multiple ulcers often appear in the juxta-pyloric region. But while erosions readily form in stomachs and become full fledged ulcers these ought to heal and do unless other factors intervene. One of the beliefs of the hour is that spastic contraction of the stomach is a factor. Increased acidity induces such contractions but so might some central nervous influence. But it is also held that the erosion comes first and provokes contractions which shut it off in a measure from the acid contact. The possibility of a vicious circle in this connection is not to be lost sight of. In some gastric ulcers in animals the presence of circulatory disturbances—embolism, infarction, hemorrhage—seems to be an important factor while mechanical causes are lacking. It seems certain that such primary lesions also occur in man and that they are more or less vulnerable to the action of the gastric juice—*Medizinische Klinik*, January 2, 1926.

The Healing of Gastric Ulcers—In a previous article Burrill B. Crohn, Samuel Weiskopf and Paul W. Aschner reported a series of duodenal ulcer cases which under medical treatment showed relief of symptoms, the roentgen-ray examinations showing a gradual diminution and final disappearance of the ulcer niche. As a result of further observations during the past year, they now (*Archives of Internal Medicine*, February 15, 1926, xxvii, 2) state that in certain types of gastric ulcer, a like process of healing also takes place following the institution of medical treatment. In two cases in which partial gastrectomy was performed for gastric ulcer, operation was timed to take place at the end of a course of preliminary medical treatment. The specimens removed showed these ulcers in the last stage of healing. In one case, roentgen-ray examination just before operation showed the disappearance of the niche that had been present. So-called "essential gastric hemorrhage" cases, if operated on soon after the hemorrhage, may show negative findings, if followed over a course of years they may eventually be demonstrated to be true ulcer cases. It is suggested that the negative findings at the first operation are due to the rapid healing of the ulcer after hemorrhage. The rapid regression of ulcers in the intermission period will explain many of the negative findings at exploratory laparotomy in cases with a suggestive ulcer history. In a series of such cases in which operation was done at a later date during recurrence of the symptoms, inspection revealed a definite ulcer. The failure, therefore, to demonstrate an ulcer at laparotomy may be due at times to the

tact that the operation is performed at a period in the life cycle of an acute ulcer when rapid regression and healing have obliterated the ulcer crater and made the lesion impossible of discernment

Functional Causes and Treatment of Epigastric Distress — Alexander McPhedran (*Canadian Medical Association Journal*, February 20, 1926, xvi, 2) states that the most frequent sufferers from epigastric distress are those of nervous temperament. The trouble is usually attributed to gastric acidity, but there may be a low acidity. The discomfort depends on the irritability of the gastric nerves, or rather of their centers in the spinal cord. Acidity depends on the pneumogastric nerve, which if irritated will cause excess secretion, and this in turn frequently excites the spinal centers and induces gastric spasm, as proved by the prompt relief afforded by bicarbonate of sodium, magnesia, or other antacid. Many cases are due to chronic focal diseases within the abdomen, especially of the gall-bladder, the appendix, and the stomach itself or the duodenum as in chronic ulcer. They all increase the irritability of the spinal and pneumogastric centers and cause marked gastric symptoms. It is, therefore, of first importance that a searching examination be made not only of the appendix and gall-bladder, but of the duodenum and stomach, resorting to the aid of x-ray examination. Eye strain is not a rare cause, and frequently there is consciousness of action of the heart, with irregularity, premature ventricular systoles being the most frequent. The author cites two cases which were associated with anginal attacks which were completely relieved following treatment of the gastroenteric system. Esophageal gastric spasm may also be excited by angina pectoris, as the irritability of the cardiac centers in the spinal cord may and usually does extend to the centers related to the esophagus and stomach. Treatment under all these circumstances calls for relief of the spasm. For that purpose about 15 grains or more of bicarbonate of sodium in half a pint of water, given an hour before each meal, lessens acidity and flushes out the stomach contents. The bowels require to be moved efficiently without purging, and the diet should be restricted. The aim is to reduce the stimulus to gastric secretion. Strontium bromide, tincture of belladonna and similar remedies may be added with benefit. In all cases the psychic condition should have careful attention. Assurance of recovery may of itself relieve the symptoms, as proved in one of the illustrative cases which the author cites.

Nonsurgical Duodenal Drainage — Rausch, assistant to Professor Koranyi of Budapest, writing on this subject in the *Klinische Wochenschrift* of January 29, 1926, points out that the

tion of the Charlatan

ome evidence, more or less cogent, of negligence which you may consider for what it is worth, along with all the other evidence in the case."

The Court of Appeals reversed the judgment of the trial court because of the instruction that the violation of the Public Health Law was "some evidence of negligence." A very strong dissent was written by Judge Crane. Thus, the reversal was based solely upon the charge of the trial court, and, therefore, did not involve the merits of the plaintiff's claim in any way.

This charge of the court, which was disproved, is of peculiar interest to the sponsors of the Medical Practice Act now pending before the legislature, inasmuch as the adoption of the proposed act would permit in future trials the charge on the jury which was condemned by the Court of Appeals. Subdivision 6 of Sec. 174 of the new Medical Practice Act provides:

"In any action for damages for personal injuries or death against a person not licensed hereunder for any act or acts constituting the practice of medicine as herein defined, when such act or acts were a competent producing proximate or contributing cause of such injuries or death, the fact that such person practiced medicine as herein defined without being duly licensed shall be deemed prima facie evidence of negligence."

Thus in future trials, where other dupes are beguiled into the clutches of the chiropractor and suffer as a result paralysis, broken bones, death or other injuries, they may establish a prima facie case by showing that they were injured by a chiropractor and that such chiropractor was not licensed to practice medicine. The new Medical Practice Act for this reason, among many others, is entitled to the support of every intelligent person in this State, to the active backing of the licensed medical practitioners, and to the fair consideration of the legislature.

Inasmuch as the sole question before the Court of Appeals in the Shyne case was the correctness of the trial judge's charge and there was not and could not be any dispute there as to the questions of fact, and both the prevailing and dissenting opinions are in accord that the chiropractor, in treating his patient, had committed a criminal offense, *to wit*, the crime of practicing medicine without a license, we shall discuss indiscriminately the statements of fact contained in both the prevailing and dissenting opinions.

The Painful and Latent Phases of Peptic Ulcer—Walko of Prague has made an attempt to fathom the mystery of the latent periods of peptic ulcer by extensive research with roentgenography (*Mittheilungen aus den Grenzgebieten d. Medizin und Chirurgie*, xxxix, 1, 1926). Apparently he has not succeeded, but he has shown that there are no changes either in the direct or indirect roentgen evidence during the transition from active to latent and latent to active phases. He has therefore been forced to the conclusion that the only changes are in the sensibility of the nerves of the vegetative system, although he does not conjecture how the failure to register pain can be brought to pass—whether exhaustion is possible, for example. His summary is in part as follows: The secretory and motor behavior of the stomach shows no evidence of change at any time (indirect signs). Periodicity, alternation of pain and quiescence, is due to alterations neither in the stomach nor in the ulcer itself, and the alternation must therefore be of neurogenic origin. This is not denying that changes do occur in the roentgen signs during the march of the ulcer, but they do not at all harmonize with the changes in painful sensations, save only in such exceptional cases that the agreement can be explained only by coincidence. In fact the changes are often directly opposed to the expectation, for they may be more marked during the quiescent period and less marked in the active period. In other words the cycle of pain has nothing in common with the course of the ulcer. To some extent this is true of all clinical evidence, for we often find little agreement between clinical and x-ray evidence. But this does not mean that the latter is of no value. It is true that we cannot always tell an active ulcer from a scar, but by means of the rays we can show that an apparently healed lesion is only latent.

The Comparative Pathology of Gastric Ulcer—According to Hirsch all of the domestic animals are liable to suffer from gastric ulcer, and especially is it found in the rennet stomach of the young calf although apparently never so long as it is milk fed only. This affection has always been as much of a puzzle to veterinarians as it is to physicians, but a comparative study of human, animal, and experimental ulcer ought certainly to increase our present knowledge. It is evident, for example, that there are separate types of peptic ulcer. The duodenal ulcer may be regarded as one and is extremely rare among the animals. In the stomach the great incidence of ulcer in the so-called "thoroughfare" of the organ—the tract which beginning at the cardia traverses the lesser curvature to reach the pylorus and comprises the first portion of the duodenum—appears to show that thin ulcer has a different etiology or pathology from that of ulcer elsewhere in the organ, and there is reason to

believe further that ulcer on the near side of the pylorus has some special traits. It is often multiple and doubtless has a mechanical casual factor. When the calf passes from milk to coarse, rough fodder multiple ulcers often appear in the juxta-pyloric region. But while erosions readily form in stomachs and become full fledged ulcers these ought to heal and do unless other factors intervene. One of the beliefs of the hour is that spastic contraction of the stomach is a factor. Increased acidity induces such contractions but so might some central nervous influence. But it is also held that the erosion comes first and provokes contractions which shut it off in a measure from the acid contact. The possibility of a vicious circle in this connection is not to be lost sight of. In some gastric ulcers in animals the presence of circulatory disturbances—embolism, infarction, hemorrhage—seems to be an important factor while mechanical causes are lacking. It seems certain that such primary lesions also occur in man and that they are more or less vulnerable to the action of the gastric juice—*Medizinische Klinik*, January 2, 1926.

The Healing of Gastric Ulcers—In a previous article Burrill B. Crohn, Samuel Weiskopf and Paul W. Aschner reported a series of duodenal ulcer cases which under medical treatment showed relief of symptoms, the roentgen-ray examinations showing a gradual diminution and final disappearance of the ulcer niche. As a result of further observations during the past year, they now (*Archives of Internal Medicine*, February 15, 1926, xxxvii, 2) state that in certain types of gastric ulcer, a like process of healing also takes place following the institution of medical treatment. In two cases in which partial gastrectomy was performed for gastric ulcer, operation was timed to take place at the end of a course of preliminary medical treatment. The specimens removed showed these ulcers in the last stage of healing. In one case, roentgen-ray examination just before operation showed the disappearance of the niche that had been present. So-called "essential gastric hemorrhage" cases, if operated on soon after the hemorrhage, may show negative findings, if followed over a course of years they may eventually be demonstrated to be true ulcer cases. It is suggested that the negative findings at the first operation are due to the rapid healing of the ulcer after hemorrhage. The rapid regression of ulcers in the intermission period will explain many of the negative findings at exploratory laparotomy in cases with a suggestive ulcer history. In a series of such cases in which operation was done at a later date during recurrence of the symptoms, inspection revealed a definite ulcer. The failure, therefore, to demonstrate an ulcer at laparotomy may be due at times to the

know what the disease is, is a contention which might have gained credence in the unenlightened mediaeval centuries, but that such a contention should be seriously put forth in this enlightened day, with all the slow and painful discoveries of bacteria and disease carefully evolved by scientists who are interested in mankind rather than their pocketbooks, is an insult to the intelligence of the people of this State and especially to the legislature, one of whose primary duties is the preservation and safeguarding of the public health.

The true nature of the chiropractic doctrine was never better stated than by Judge Crane in this most recent judicial exposure of chiropractic fallacy. Judge Crane, one of the most eminent jurists of our State, had thus to say:

"The theory of the chiropractics is that most, if not all, diseases come from pressure on the nerves caused by vertebra deviating from the normal. The treatment consists in restoring the vertebra which is out of alignment to its proper place to relieve the pressure. This is done by palpitating the spinous processes and pushing or manipulating the vertebra into place. The chiropractic claims to be able to treat and cure many diseases in this way. One of the defendant's chief experts in this case stated that the treatment consists entirely in adjusting the vertebrae which are found out of alignment to normal position. In this way, he stated, cancer of the stomach and liver can be cured, tuberculosis, smallpox, diphtheria, scarlet fever, diabetes and other diseases. *The chiropractic does not believe in the theory of disease.*"

Why is it necessary to say more? How could he be said? Think of it! A cult of men not educated to practice medicine, possessing no qualifications for this purpose, not only lacking the requisite knowledge and of course never having had their educational qualifications tested by a state preying upon human credulity! Of these ignorant quacks boasting that they

break the law and of the large revenue which they derive from their lawbreaking—these ignorant charlatans who deny the existence of the germ theory! It is high time that the people of this State should be aroused to this evil, this crying danger to the public health. This is no contest between licensed physicians and chiropractors, as the latter's representatives so frequently assert in the halls of the legislature and elsewhere. The licensed physician has no interest in the chiropractor except his interest as a citizen to see that the lawbreaker, the charlatan and the quack should be brought to justice. The time for action has come. The way is open. The law is clear. All that is necessary is the energy requisite to drive these medical bandits from our midst. If this is not done fearlessly, persistently and courageously, the time may come when the health of the whole people of the State of New York will be endangered by a plague of typhoid, scarlet fever, diphtheria, smallpox or other contagious disease. The chiropractor denies the existence of the germs which cause these dread diseases. He blatantly asserts that he is able to treat them, although he does not know what they are or who is suffering from them.

The new Medical Practice Act, if adopted, will furnish a new and more powerful weapon with which to put down this dangerous invasion against the health of our people. Doctors should support it, laymen should support it, all who believe in knowledge as opposed to ignorance, honesty as opposed to fraud, science as opposed to charlatanism and quackery, health as opposed to disease, cure as opposed to continued illness, should support the new Medical Practice Act. The case of Brown vs. Shyne illuminates and demonstrates the need of action.

No case on record has more clearly exposed the dangerous fallacies from which a large group of charlatans in this State derive substantial income. In the prevailing opinion Judge Lehman said

"The provisions of the Public Health Law prohibiting the practice of medicine without a license granted upon proof of preliminary training and after examination intended to show adequate knowledge, are of course intended for the protection of the general public against injury which unskilled and unlearned practitioners might cause."

As already pointed out, the prevailing opinion unhesitatingly condemned chiropractor Shyne for having committed a criminal offense. Judge Lehman expressed it in this language

"The defendant had no license to practice medicine, yet he held himself out as being able to diagnose and treat disease, and under the provisions of the Public Health Law (Cons Laws, ch 45) he was guilty of a misdemeanor. The plaintiff became paralyzed after she had received nine treatments by the defendant."

Thus once more we have a judicial determination that the chiropractor who holds himself out as being able to diagnose and treat disease is a criminal, he is a lawbreaker, he has done that for which he could be tried, convicted, sent to jail and fined. It is valuable to have this new judicial condemnation of the chiropractor, but as we pointed out in one of our recent editorials, the courts of this State have long adhered to this conclusion. That conclusion was reached in May, 1914, when chiropractor Leo E. Ellis, who was a graduate of the Davenport University of Chiropractics, was charged with the crime of practicing medicine without a license and was convicted of that crime. Again, in November, 1920, the conclusion was reached when a chiropractor treated an eight-year-old girl suffering from pericarditis and pleuritis and the patient died from his treatment. It was again reached

May, 1921, when a chiropractor who was entering the daytime as a clerk in a baggage local depot and who spent his evenings visiting spines was convicted of the crime of practicing medicine without a license. Ernest G. Meyer, a Palmyra physician, was involved in the injuries to a young child, which were caused by the use of a "thoracic" machine, which was used by Hagarty and a chiropractor, in the treatment of the child. The affirmation of the conviction was referred to the Supreme Court.

1. The types of peptic ulcer are regarded as one and the same in the animals. In the stomach the ulcer in the so-called "thoracic" organ—the tract which begins at the lesser curvature and reaches the first portion of the duodenum—appears to show that thin ulcer has a different etiology or pathology from that of ulcer elsewhere in the organ, and there is reason to

the Universal Chiropractic Association, made this admission under oath

"Q And yet in the face of the fact that Mr. Meyer said he didn't know and never knew until after the death of the child that the child had diphtheria, you still say that your answer does not consider that of any moment? A Yes, sir"

In the Shyne case this authoritative language from the United States Supreme Court in the case of *Dent vs. West Virginia*, 129 U. S. 114, 122, was quoted

"Few professions require more careful preparation by one who seeks to enter it than that of medicine. It has to deal with all those subtle and mysterious influences upon which health and life depend, and requires not only a knowledge of the properties of vegetable and mineral substances, but of the human body in all its complicated parts, and their relation to each other, as well as their influence upon the mind. The physician must be able to detect readily the presence of disease and prescribe appropriate remedies for its removal. Everyone may have occasion to consult him, but comparatively few can judge of the qualifications of learning and skill which he possesses. Reliance must be placed upon the assurance given by his license, issued by an authority competent to judge in that respect, that he possesses the requisite qualifications. Due consideration, therefore, for the protection of society may well induce the state to exclude from practice those who have not such a license, or who are found upon examination not to be fully qualified."

Despite this authority from the highest court of our land that those who practice medicine must have their qualifications tested by the state, the chiropractors who never have had their qualifications tested by the state, continue to flourish and even to boast of the number of "patients" whom they treat

At the hearing before the Joint Committee of Public Health of the Senate and Assembly held in Albany on the 3rd of March, 1926, the counsel for the State Chiropractic Association made the bold and frank admission that chiropractors in carrying on their practice, violate the law, and this admission was made while arguing that the chiropractors should not be prevented from carrying on their work and that the evidence of the value of their practice to the public health was shown by the number of persons who had paid money to receive chiropractic adjustment. The same argument might be made with equal force against the passage of the blue sky laws. Those who make a living by imposing upon the ignorance of widows and orphans and inducing them to buy fake stocks and bonds in non-existent mines might with equal force contend that their work of fleecing the public should not be interfered with because so many of the public have been willing to part with money for the securities thus purveyed.

The practice of chiropractic, in plain English, is pure quackery. It rests upon no scientific basis and has never been treated by spine manipulations and that to treat disease it is not necessary to

A LETTER TO A LEGISLATOR

MY DEAR SIR

I have read with much interest the bill amending the public health law, whereby the practitioners of Optometry are to have the privilege of prefacing their names with the word "Doctor." Honestly, do you not think this bill is working in the wrong direction? I do, for this reason. For over two hundred years, Universities have been conferring upon graduates, who took special work involving in most instances more than four years of collegiate attendance, the degree of Doctor. Whether it be the Doctor of Philosophy, Doctor of Civil Laws, Doctor of Dental Surgery, Doctor of Medicine or what not, has made little difference in the requirements. Furthermore it has always stood as a respected degree. English and Provincial as well as Colonial Universities do not confer the degree of Doctor of Medicine without the candidate having spent additional time or done additional work of note, beyond that required for his ordinary medical education. Granting the degree of Doctor to anyone fulfilling less rigorous requirements tends to cheapen the degree and lower the educational standards of the state.

On the average the public is undiscerning. Chiropractors hereabouts have been in the habit of preceding their names with the word Doctor, or following it with the title "Doctor of Chiropractic." In some instances they have used the initials, D C, but have generally changed over to the former. I have in my case histories numerous instances of apparently intelligent people who went to these men supposing that they were full fledged Doctors of Medicine. Just as another local illustration, when the present Director of the New York State Experimental Station came to town, some misguided individual inserted his name in the Telephone Directory as Dr. Thatcher. It was not long before Dr. Thatcher who happened to be a Ph D, not an M D, was called in the middle of numerous nights to attend obstetrical cases, contagious diseases, and accidents. Needless to say the telephone directory was promptly corrected.

One of our local shoe stores has an itinerant traveling salesman who came through as a representative of a certain brand of arch props. For some unholy reason he calls himself "Doctor" and the public swallow it. The letters which he writes to his customers would indicate that he progressed as far as the sixth grade in school and yet they call him "Doctor." Undoubtedly he will be entitled to the name, if the podiatry bill goes through and becomes a law.

This town is so full of Doctors of various types that it is almost a disgrace to be one. Some time ago a colored bootblack, sensing the trend of times, decided that he would be a "Doctor" too. He had his sign rearranged to read "Art

Kinney, Doctor of Bootblackening." This not only got him considerable business, but also earned him the title of "Doc" which he still enjoys.

I am wondering how it would be if some of our medical members of the legislature were to introduce a bill, granting a degree to each Justice of the Peace on his qualifying for office and giving him the privilege of hanging out a sign something like this

'JUDGE IGNORAVIUS JONES
JUSTICE OF THE PEACE

All kinds of tests applied

Broken contracts mended—All we need is the pieces

Never-ship agreements prepared while you wait

Snappy style—All work guaranteed

See us first—Why not now?"

"What would you think of such a proposition? If it is "sass for the goose" why not "sass for the gander." While we are at it, why not allow every notary public to practice in all but the Supreme Court on the same footing as the now authorized legal profession?

If the medical profession is to occupy the respectable position which it desires, if it is to continue as the guardian of the health of the public, progressive in matters of public health, sanitation, and disease prevention, and be of any value to the body politic, it can only do so by receiving at the hands of the government such recognition as it justly deserves, such protection as will insure its permanency, and such assistance as will encourage its further development.

I trust that we may have your assistance and cooperation, so that the proposed Medical Practice Act of 1926 may be enacted into law. With this bill on the statute books we feel that the position of the medical profession is assured, and that for many years to come conditions will be so covered as to make amendments to the law unnecessary.

H. J. KICKERBOCKER, M.D.,
Chairman Legislative Committee
Ontario County Medical Society

Editor's Note—This letter is an excellent example of a form of communication that will be likely to have an effective appeal to a legislator.

It offers a clear-cut argument, and backs up the reasoning with striking examples of which the legislator himself may be aware.

It more doctors will take the trouble to compose and send letters like this one, legislators could give definite reasons for supporting a practice of medicine bill that is wanted by the doctors and the thinking public.

LEGISLATION

HENRY L. K. SHAW, M.D.
Chairman, Committee on Legislation

LEGISLATIVE PROGRESS

The condition in Albany in regard to medical legislation has never been more favorable for maintaining and raising the standards of the practice of the healing art. Legislators are asking for enlightenment regarding proposed bills, and those who seek special privileges by lowering medical standards are strangely unassertive. It may be that they exposed their own ignorance in the two hearings on the chiropractic and the Practice of Medicine bills.

The Practice of Medicine bill has been made the subject of minor amendments which, however, have not affected its main features. It is receiving the support of county tuberculosis committees throughout the State. The State Charities Aid Association in its anti-tuberculosis crusade is dependent upon a skilled medical profession for the detection and treatment of the cases, and none know better than the members of the county committees how necessary it is to have skilled doctors to diagnose the cases and to supervise their management. It is therefore entirely proper that the members of the local committees should inform the legislators regarding their wishes, and should request them to support the Practice of Medicine bill. Legislators confess their surprise and gratification in the interest in the bill taken by laymen. Legislators wish to maintain a high standard of medical practice, but

this is the first year that their constituents have told them of the popular support of the bill. The very great mass of letters in previous years have been from chiropractic clients who were opposed to the Practice of Medicine bill, but this year the chiropractors seem to be silent, and the lay supporters of the bill are active. The State Charities Aid Association deserves the thanks and congratulations of physicians for its active support of the measure to set a high standard for medical practice.

The situation in regard to Workmen's Compensation bills is uncertain. The groups to be satisfied are so numerous that their agreement on any broad bill of constructive importance is doubtful, especially is this the situation in regard to the establishment of a medical council and a system of medical inspectors.

The bill permitting the Medical Society of the State of New York to establish trustees has passed the Assembly and has reached the third reading in the Senate. It will probably pass. Only one legislator spoke against it to question the use to which the funds of the Society will be put.

Bulletins four and five have been prepared and sent to the chairmen of the county legislative committees.

A PASTOR'S OPINION OF BASIC MEDICAL TRAINING

Dr. S. Parkes Cadman, Pastor of the Central Congregational Church of Brooklyn, contributes to the New York *Herald-Tribune* a daily column of answers to questions in civics, morals, and religion, and frequently includes medical topics in his discussion. His column in the *Herald-Tribune* of February 16th contains illuminating remarks on the basic educational requirements for practicing medicine. He was asked:

"If you had been a successful practicing chiropractor for nearly ten years and if the American Medical Society, authorized by the State, said you could not continue to practice unless you complied with certain laws which practically destroyed your science, what would you do?" Dr. Cadman's answer was as follows:

"I should conform with the laws in question.
"The general principle underlying the training

of candidates for the learned professions is that they shall pursue certain recognized studies.

"These studies are not confined to the teachings of any one school of law or medicine or divinity. They include as far as possible the entire realm of these branches of learning.

"Nor will the state license a candidate to practice law, medicine or dentistry until it is acquainted through prescribed sources with the extent of his knowledge of his calling.

"Once his knowledge is reported satisfactory, the state does not interfere with the practitioner's opinion. He may be a chiropractor still, and a better one because of his broader training.

"The inquirer has to face a condition and not a theory. So long as the state must protect the life of the citizen it will insist that those who profess, as he does, to heal diseases and delay death shall meet all its requirements."

Senate Introductory No 920—Mr Karle introduced a bill, copy of which is enclosed, regulating the occupation of hairdressers and cosmetologists, providing for licensing them and establishing schools. It is exceedingly interesting to note how broad the Public Health Law is growing to be.

Senate Introductory No 945—A bill introduced by Mr Higgins amends section 318-a, Public Health Law, by providing books and records showing sales of hypodermic syringes

and needles shall at all times be open to inspection by proper officers

HEARINGS

None scheduled for this week and we are advised that the calendar for next week has not been prepared

HENRY L K SHAW,
ARTHUR W BOOTH,
CLARENCE F GRAHAM,

Committee on Legislation,
Medical Society of the State of New York

BULLETIN NO 5

March 17, 1926

Our Trustee Bill, Assembly Introductory No 725—concurrent Senate Introductory No 532—has passed both the Assembly and Senate and gone to the Governor for signature

The Webb-Loomis bills—Assembly Introductory No 955, Senate Introductory No 717—have been reprinted so that they are now identical. Each contains a provision for the physiotherapy technicians. A copy of the latest print is enclosed. These bills will be acted upon in both committees this week and it is hoped may be reported out by the end of the week or Monday of next week. If they come out, we shall send you a special bulletin. By all means, this is the time when every physician should be doing his utmost to secure support for our bill. Remember that letters from influential lay persons are considered exceedingly valuable by the legislators. Leave no stone unturned, secure the co-operation of every organization that may be influential in your district.

Let us call your attention again to the willingness of the Tuberculosis and Public Health Committees throughout the State to assist in bringing support to this bill. Evidence of the activities of some of these organizations is already apparent at the Capitol. If your Society has not as yet gotten in touch with your local Committee on Tuberculosis and Public Health, we suggest that you do so at once and direct them as to how they can exert their greatest influence. Chambers of Commerce, through their Public Health Committees, should be asked to write to their legislators, Women's civic clubs, particularly the League of Women Voters, should be asked to lend their support. No voter should be neglected. Quality, of course, has its value, but quantity of support is also considered by legislators when framing their opinions.

Assembly Introductory No 65—Miller—concurrent Senate Introductory No 35, Workmen's Compensation bill, has been amended by Mr Miller and recommitted. The amendment makes possible the appointment of an osteopath to the

medical council and rewrites in a clearer way that portion where it provides that physicians applying for positions in the compensation division of the Department of Labor, shall come to Albany for a personal interview before receiving appointment. You will notice this amendment at the bottom of page 8 and the top of page 9. You will notice another important change on page 7 under 1 of section 78 has been rewritten.

Assembly Introductory No 331—the Miller eye bill (concurrent Senate Introductory No 184), is being rewritten by Dr Snell and very likely the amendments will be reported in the next week.

Assembly Introductory No 552—concurrent Senate Introductory No 375, a bill which would provide for employment of a physician to examine prisoners as they are entered at the county jail—which we reported in our last Bulletin as progressing²—has been passed in the Assembly and advanced to third reading in the Senate.

Assembly Introductory No 557—co current Senate Introductory No 357, habit forming drugs, was reported out by the Senate committee and has advanced to third reading.

Assembly Introductory No 1300—Ricca—has undergone another change, we are told. This bill originally made provisions for orthopedistry and before it received a hearing it was amended by substituting the word "bandagistry" for "orthopedistry," and now it seems that the name has been changed to "bandagery."

Senate Introductory No 945—which we mentioned in our last Bulletin—providing that books and records showing sales of hypodermic syringes and needles shall at all times be open to inspection by proper officers, has advanced to third reading. It has not yet appeared in the Assembly.

Following is a list of the bills introduced since our last communication

IN ASSEMBLY

Assembly introductory No 1350—(concurrent Senate Int No 968—A bill introduced by Mr

BULLETIN NO 4

March 9, 1926

The only bills to show any activity during the past week are the following

Assembly Introductory No 725—Senate Int No 532—our Trustee Bill, still rests with the Senate Judiciary Committee, but our information now is that it is being reported out today

Assembly Introductory No 76—Senate Int No 50—providing for licensing of persons making bacterial counts of milk and cream. Passed and referred to Governor, March 2nd

Assembly Introductory No 368—Senate Int No 147—announced in our first publication. The program has been amended so as to include specifically laboratory workers who are obliged to handle pathogenic micro-organisms.

Assembly Introductory No. 552—Senate Int No 375—requiring county jail physicians to examine prisoners, has progressed much more rapidly than we prophesied in our comment in The Program. It has been reported out in both Houses and in the Assembly was advanced on March 4th to third reading. Since the bill is moving so nicely, those who have the opportunity should exert their influence to have it passed

Following the hearing on Wednesday, the Medical Practice Act was amended by its introducers so as to include the provision for the organization of physio-therapists. This was done before the physicians who attended the hearing had an opportunity to discuss the effect such an amendment might produce. When they discovered the bill was printed, they regretted the speed because it became very apparent that the amendment was not acceptable to the medical profession or to the Society of Physio-therapists whom, it seems, were not consulted when this amendment was drawn. Leaders of this Society have requested that the amendment be stricken out and they be given an opportunity to prepare a bill of their own and this will be done, after which the bill be printed again and a copy sent you. There is still a surprisingly small amount of opposition manifested to our bill, both Senators and Assemblymen tell us that they are receiving letters urging the passage of the Medical Practice Act and practically none in opposition to it. This may or may not be a good sign

Following is a list of the bills introduced since our last communication

Assembly Introductory No 1247—Introduced by Mr Berg, would amend the Public Health Law so as to permit optometrists to use the title "doctor" providing they follow their name with the word "optometrist". As you can readily see, this is a companion bill to the podiatrist bill. Last week we appeared at the hearing against the podiatrists, urging that if chiropodists and podiatrists were permitted to use the title

"doctor," it would be establishing a precedent which other groups would not be slow in employing—and this bill is a confirmation of that prophecy. The optometrists feel that they have an equal right to be known as doctors, as the chiropodists. Our contention before the hearing was that none but men who have taken the regular four-year course in medicine and have complied with conditions laid down by the University of the State of New York, should be permitted to use the title "doctor". We gave as our specific reason that, to a lay person, the word "doctor" had just one significance—and that was that the individual using the title was qualified to examine persons and diagnose ailments and that podiatrists or any other group who may, so far as educational qualifications go, be authorized to practice on a particular part of the body, are, nevertheless, not qualified to make a complete study of the human body and, therefore, the use of the title "doctor" would be misleading. We shall enter this same plea in opposition to this bill of Mr. Berg's

Assembly Introductory No 1267 (concurrent Senate Int No 921)—Dr Lattin introduced a bill relative to certificates and reports to be made by counties receiving State aid for public health work

Assembly Introductory No 1292 (concurrent Senate Int No 946)—Dr Lattin introduced an amendment to the Public Health Law asking that the holder of a license to practice medicine in a foreign country, where requirements are not lower than those required for this State, be permitted to practice here. This is a variation of the Coughlin bill, Assembly Introductory No 132 which would permit holders of licenses granted in other states, to practice in this State

Assembly Introductory No 1300—Mr Ricca has revised his orthopedistry bill by dropping the word "orthopedistry" and substituting the word "bandagistry" and by the addition of this clause "nor shall he have the right to diagnose ailments or diseases of the human body". It is the hope of the introducers that these amendments will meet two of the important objections raised by the opponents at the hearing, first, that the name "orthopedistry" suggested an orthopedic surgeon and by substituting "bandagistry" they felt they had overcome that difficulty, and, second, that the bill as it was worded would permit manufacturers of splints to apply them without medical advice and the added clause is intended to overcome that difficulty

Assembly Introductory No 1303—Mr Rosenman adds a new section to the Penal Law requiring physicians or hospital superintendents to report to police authorities all cases for treatment of wounds caused by firearms

This year a very great deal has been accomplished in the way of public interest by an appeal to lay organizations interested in matters of public health. Undoubtedly the lay public are beginning to realize that it is their responsibility to protect ignorant people against deceit and fraud in matters pertaining to treatment of illness. The Tuberculosis and Health Association of the State has been most active in presenting arguments in favor of this bill at public meetings and at legislative hearings. The time is now at hand to ask you to do your share. This duty is self-evident to every thinking member of the medical profession. You can help materially in the following ways:

First—Write your Senator and Assemblyman, telling him that you personally consider that this bill is a measure which demands enactment into

law for the protection of public health and the elimination of quackery in the State.

Second—Ask members of your family and friends to write similar letters to the Legislators, urging their favorable action when this bill comes up for vote.

Third—Be well acquainted with the bill and with the situation as regards quackery and cultism now existing in New York State so that you can take opportunity to present the right side of this bill to laymen. If you are a member of a hospital staff, urge your staff, hospital executives and hospital boards of governors to actively take an interest in this legislation and write to their legislators reviewing their interest and urging the enactment of the measure into law.

W A CALIHAN,
Chairman

JEFFERSON COUNTY MEDICAL SOCIETY

March 11, 1926

WHEREAS, The members of this Society have absolute confidence in the committees of the county and State Societies representing them, in matters of legislation, and

WHEREAS, We feel that the present amendment to the Medical Practice Act, as introduced into the legislature by Mr Loomis, and as published in the State Medical Journal of March 1st, is as near perfect as it can be,

Be It Resolved, That this Society vote its approval of said amendment to the Medical Practice Act,

Be It Resolved, That this Society, through its

members, request influential citizens of this district to write their representatives to favor the passage of this bill, and

Be It Further Resolved, That a copy of this resolution be sent to the Senator and Assemblyman from this district to the President of the State Society, and to the chairman of our state legislative committee.

The above resolution was offered by the chairman of our local legislative committee, on the above date, and *passed unanimously*.

(Signed) PAGE E THORNHILL,
Secretary pro tem

OTSEGO COUNTY MEDICAL SOCIETY

The quarterly meeting of the Otsego County Medical Society was held March 9th, 1926. The session was called at 4 30 P M in the parlor of the Hotel Fenimore, Cooperstown. Dr R W Ford, President in the chair. Minutes of the last meeting were read and approved.

The application of Dr Alex F Carson was received and approved for membership. Dr F H Marx, acting chairman of the Legislative Committee made a report on pending bills before the legislature.

A motion was made, seconded and carried that the Medical Society of Otsego go on record as approving the Assembly Bill No 1011, to amend the public health law, and that notice should be sent to our Senator and assemblyman urging them to approve the same.

A motion was made, seconded and carried that the Society go on record as approving the Assembly bill No 65 510 known as the Workmen's Compensation Law.

The Society also endorsed the plan of toxinitoxin treatment for Diphtheria, the examina-

tion of children of pre-school age, and the work of the Junior Project.

Dr William C Garvin, Superintendent of the State Hospital in Binghamton, N Y, read a paper on "The Early Diagnosis of General Paresis".

Dr Hugh S Gregory, of the State Hospital presented a series of lantern slides showing the pathological changes in the brain and cord as a result or cause of Paresis.

Because of the bad condition of the roads only a few members were present.

Drs Cruttenden Atwell, Bissell, Lanning and Tyrone of Cooperstown. Dr R W Ford of Otsego, Dr F L Winsor, Laurens, J P Hoyle, Fly Creek. Dr W R Seeber, Milford, Drs Champlin, Marx and A H Brownell of Oneonta, Dr William C Garvin and Dr Hugh S Gregory of Binghamton.

Announcement was made of a series of lectures on obstetrics to be given in the Elks Home each Tuesday evening at 7 P M, beginning March 30th.

Evans, would amend section 82 of the Insanity Law by providing for trial by jury to determine question of insanity

Assembly Introductory No 1351—(concurrent Senate Int No 967)—Also by Mr Evans, would amend section 81, Insanity Law, relative to qualifications of examiners in lunacy "The qualifications of medical examiners in lunacy certified after date from which this act shall take effect shall be that he or she must be a reputable physician, graduate of an incorporated medical college, who has been in actual practice of his or her profession at least three years, and shall have at least two years actual experience in the care and treatment of the insane in an institution for the insane" This, as you see, limits the examiners in lunacy to those who have served at least two years in an institution for the insane

Assembly Introductory No 1353—A bill introduced by Mr Fay, would amend the Civil Practice Act by providing that malpractice suits must be commenced within one year instead of two years, as the law now reads Copy of this bill is enclosed

Assembly Introductory No 1377—A bill introduced by Mr Doyle, would amend the Workmen's Compensation Law by authorizing injured employee, at expense of employer, to employ physicians and surgeons

Assembly Introductory No 1410—Introduced by Mr Thomas, would amend the Public Health Law relative to the powers and duties of local health boards The important part of the amendment is that it provides for the appointment by a health officer of a physician to act as health officer during his temporary absence or incapacity on account of illness

Assembly Introductory No 1416—A bill introduced by Mr Hofstadter, would amend the Public Health Law by authorizing any woman filling prescribed conditions, to practice as a dental hygienist

Assembly Introductory No 1427—Introduced by Dr Lattin, would amend the General Business Law relative to licensing employment agencies by bringing under provisions agencies providing employment for nurses This bill was prepared by the State Medical Society at the suggestion of the special Committee on Nursing A copy is enclosed

Assembly Introductory No 1457—Introduced

by Dr Lattin, would amend the Public Health Law by authorizing board of supervisors to abolish any general health district at any time after two years following its establishment and after a public hearing, and relative to salary of health officer for general district

Assembly Introductory No 1526—Introduced by Mr Alterman, would amend the Penal Law by providing that no experiments or investigations for scientific purposes shall be made upon a living dog When the bill is printed, a copy will be forwarded This is our annual antivivisection bill, but it has appeared so late this year that we are inclined to think it will get but slight consideration It will be almost impossible to arrange a hearing

HEARINGS

The following hearings were announced on Monday

March 16th—Assembly Int No 1303—Rosenman—Penal Law, wound firearms

March 17th—Assembly Int No 1025—Laudau—Health Law, X-ray treatment

March 17th—Assembly Int No 1051—Meegan—Health Law, eyeglasses, sale

March 17th—Assembly Int No 1097—Grossman—Health Law, anaesthetic

March 17th—Assembly Int No 1292—Lattin—Health Law, practice medicine

March 17th—Assembly Int No 1300—Ricca—Health Law, bandagistry

March 23d—Senate Int No 723—Cole—Educ Law, medical inspection

March 23d—Assembly Int No 1042—Rice—Schools, medical inspection

Both Houses have adopted resolutions deciding that all individual committee work will end on April 1st and after that date both Houses will proceed as Committees of the Whole That will mean that probably next week will be the last week that hearings will be held

HENRY L. K. SHAW,

Committee on Legislation

Medical Society of the State of New York

P S—Loomis Medical Practice Act and the Esmond Chiropractic Bill voted out by Assembly Committee today

LEGISLATIVE COMMITTEE—COUNTY OF MONROE

The Legislative Committee of the Medical Society of the County of Monroe has sent the following letter to each of the members

Dear Doctor

The Legislative Committee of the Monroe County Medical Society consider that it is most essential for you to take an active part in an

effort to create sentiment in favor of the *Medical Practice Act* which is before the Legislature at this session This bill, known as amendments to the Medical Practice Law, is called *Assembly Introductory No 955* The bill has been discussed at various times in the State Journal and you must be aware of its contents

EPIDEMICS OF MEASLES

Dwellers in rural districts are well aware that cases of measles come in waves or groups with considerable regularity. In sparsely settled districts the waves are several years apart, and an epidemic usually starts from an incipient case who mingles with other persons in a crowded room. The first case of a rural epidemic can usually be traced, and when the wave of cases has passed with the exhaustion of susceptible material, there may be no more cases for a decade.

In a good sized village the epidemics recur every four or five years, because of the greater number of susceptible persons and the great opportunities for contact.

In large cities measles epidemics come in alternate years, and the original cases can seldom be traced.

The Brooklyn *Eagle* of February 25th contains an article with the heading, "Measles Epidemic Is Here." It quotes Dr H. T. Peck, Assistant Health Commissioner in charge of Brooklyn Borough as saying, "It is just the biennial measles epidemic. Every two years some health statistics have been kept here in Brooklyn. Such an epidemic has occurred."

The article quoted the following table of the number of measles cases reported in recent years:

1922	12,260 cases
1923	2,635 "
1924	11,015 "
1925	1,344 "
1926 (6 weeks)	3,055 " "

It will thus be seen that in the even numbered years there are from five to ten times as many cases as in the odd numbered years.

Looking at the number of deaths there is an excess in the even numbered years, but to a lesser degree. The measles mortality figures for Greater New York are as follows:

1919	218 deaths
1920	736 "
1921	165 "
1922	977 "
1923	245 "
1924	506 "

The number of deaths from measles in Greater New York varies in alternate years with the number of cases that develop.

The weekly Health Review of the Department of Health of Detroit, Michigan, for February 27, contains a table showing the ages at which children are most susceptible to measles, and is based on a study of 305 families in which measles existed. An average of 68 per cent of the susceptible persons in those families caught measles. Of those under one year of age, 34 per cent caught it. During the ages from one to two, 59 per cent caught it, and from three to five, about 70 per cent, while from six to nine about 89 per cent caught the disease.

The lesson from these statistics is plain. Young children are more likely to die from measles than older ones, but they are also less susceptible and may more easily be kept away from cases.

The great fact about reducing the number of deaths from measles is to teach the people of the need of protecting their young children from catching the disease.

BEAUTY PARLORS

"Have you noticed that American men, women and children are three times as beautiful as they were in 1915? Oh, you must have done so, statistics show it, and so does Charles Nessler, president of the Master Hairdressers' Association of America, which is having its annual convention at the Hotel Commodore this week." These are the opening words of an article in the New York *Sun* of March 8th. The article continues:

"Mr. Nessler's figures show that there are 30,000 beauty parlors in this country, three times as many as there were in 1915, that they took in \$390,000,000 of the people's money that year and that they were patronized by 60,000,000 men, women and children.

"And 170,000 men and women are engaged in doing all these things to make the United States a prettier place to live in, and there are hundreds of schools turning out beauty graduates every

four months who are daily increasing the ranks of the profession. One school matriculates 2,000 sweet girl graduates a year.

"The average cost of a pulchritude producer's education is given by Mr. Nessler, daddy of the game, as \$250, whereas years ago the operators used to pay their pupils while they were being instructed."

These are surprising figures. Are the results worth the costs? Walk down any "Main Street" and see the clear skins, beautiful complexions, and active gaits of the women and men. The results are so striking that the beauty makers claim the glory for themselves and even to the title "cosmotologists," but they are not entitled to all the credit. Diet, exercise, and good hygienic living are more beautifying than outward applications and manipulations. Still let us thank the beautifiers for making this world a more attractive place in which to live.

NEW YORK STATE JOURNAL of MEDICINE

PUBLISHED BY THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

Vol. 26, No. 8

NEW YORK, N. Y.

APRIL 15, 1926

ANNUAL MEETING

The One Hundred and Twenty-Sixth Annual Meeting of the Medical Society of the State of New York was held during the four days, Monday to Thursday, inclusive, March 29 to April 1, 1926, in the Hotel Waldorf-Astoria, New York City. The schedule was carried out according to the program that was printed in the February 15 and March 15 issues of this Journal.

The preparations for the meeting had been well worked out and the physical accommodations gave unusual satisfaction. All the meetings and exhibits were on one floor, and doctors had no difficulty in finding one another. Familiar faces were much in evidence, and it was gratifying to note that many younger physicians were forming the habit of attendance.

The spirit of a meeting is difficult to predict. One is always safe in saying that any meeting of the Medical Society of the State of New York will be "interesting and profitable," but when the reporter is forced to use that expression, the meeting is likely to be as cold and as formal as the adjectives. The present meeting may be best described as "practical" in distinction to the idealistic, the oratorical, and the controversial. There was an absence of the spectacular, and the presence of quiet dignity and earnestness in all the meetings and discussions.

The registered attendance was 1,229, which is large for a State meeting held in New York City. It is strange that the attendance in New York is usually smaller than that in an up-State city.

The meeting of the State Medical Society embodied the four major features of the House of Delegates, the Scientific Sections, the Syphilis Exhibit, and the Commercial Exhibits.

The House of Delegates The House of Delegates held three sessions beginning at 2:30 P. M. on Monday. The delegates dined together in the early evening and then continued the session until eleven o'clock. The reports of the officers and committees were received and were referred to the usual reference committees. A significant action was the adoption of a resolution that the reports should be printed in the JOURNAL before the Annual Meeting in order that the members might come prepared to act intelligently. These

reports and a summary of the actions taken on them by the House of Delegates will appear in an early issue of this JOURNAL.

There was a feeling among the members that greater opportunity should be given to the officers and chairmen of committees to explain what they have accomplished, and what are their plans for the future. One solution would be to devote a half a day to a general session in which the officers and chairmen would present their views.

The only suggestion that aroused any considerable controversy was that regarding the acceptance of money from sources outside of the regular income of the Society. Some felt that the freedom of action of the Society would be curtailed if gifts were accepted, and on the other hand the bills for public health activities of some county societies are already being paid by gifts from individuals and lay organizations. Since the State Society is entering broader fields of service which have hitherto been left to lay organizations, the members wisely voted to refer the matter to the Council for study and action.

The spirit of leaving controversial matters to be settled after investigation was characteristic of the temper of the delegates. The House is a deliberative body rather than one of investigation, and the members avoided debates when there was not sufficient evidence for judgment. It is an excellent omen that the members were willing to leave the study of broad problems of policy to the twenty-four representative physicians who compose the Council.

The election of officers was marked by unusual harmony, and all the principal places were filled by unanimous vote without contest. The list of officers and chairmen of committees is printed on the first editorial page.

Scientific Sections Each of the seven scientific sections held three half-day sessions, but since in several instances two or more sections combined in joint sessions, the number of meetings was fourteen, at which sixty-four papers were presented. This number of papers would be just about sufficient to supply the JOURNAL with scientific material for the coming year if the JOURNAL were published monthly, but since it appears twice

BOOK REVIEWS

OTOLOGIC SURGERY By SAMUEL J. KOPETZKY, M.D., F.A.C.S., Professor Otology, Polyclinic Medical School and Hospital, N. Y. City. 102 illustrations, 4 color plates, 21 charts. Paul B. Hoeber, New York, 1925. Price, \$8.00.

This is a text devoted to the surgical diseases of the ear and their management. Early in the book it is noted that the author proceeds logically from the known pathology of the condition as a basis to the elucidation of the symptomatology, diagnosis and treatment. Because pathology is the basis for the author's discussions, the text is more readily understandable to even those who are not otologists. None of the 102 illustrations are superfluous. Each carries a real message. The photomicrographs are a contribution to the science of otology.

The author and his publishers are to be congratulated upon the style, the paper, the text and general appearance of the book. This text book stands out among those of its subject and will no doubt see several editions. To any who might be interested in diseases of the ear this book is to be recommended. M. C. M.

DISEASES OF THE NOSE, THROAT AND EAR, MEDICAL AND SURGICAL. By WILLIAM LINCOLN BALLENGER, M.D. Revised by HOWARD CHARLES BALLENGER, M.D. Fifth Edition. Octavo of 1080 pages, illustrated with 551 engravings and 32 plates. Philadelphia and New York, Lea and Febiger, 1925. Cloth, \$10.00.

It is a source of gratification to the many otolaryngologists and practitioners who have in the past enjoyed the ownership of a Ballenger that this fine text book is being continued in revised form by the son of the late William Lincoln Ballenger.

In this fifth and posthumous edition all the good features of the last edition are included. In addition, there are noticeable in many of the chapters revisions, additions and eliminations. The general arrangement of the text, the completeness of the subject matter, the paper and print, and the many illustrations make it what it has been heretofore—one of the leading text books of otolaryngology. Such chapters as those dealing with neoplasms of the larynx and the labyrinth, are examples of the completeness of the book. M. C. M.

A MANUAL OF OBSTETRICS By JOHN COOKE HIRST, M.D., F.A.C.S. Second Edition, entirely reset. 12mo. of 551 pages with 229 illustrations. Philadelphia and London, W. B. Saunders Company, 1924. Cloth, \$4.50 net.

There is little to be added to the reviewer's last remarks about the previous edition of this work, which appeared not so long ago. It is written with the concise positive style that pertains to each of these two teachers of the same family. It is a style more suited for the student than the specialist, and the book is intended for the former.

The preface to the present edition makes reference to several new developments in obstetrics that add little to its value as either they are incompletely discussed like the Kielland forceps, or might be omitted, like Potter version from such a text book.

All in all, it is one of the excellent works of its kind. E. B.

THE CULTURE OF THE ABDOMEN—THE CURE OF OBESITY AND CONSTIPATION. By F. A. HORNIBROOK. Preface by SIR WILLIAM ARBUTHNOT LANE, Bart., C.B., M.S., Consulting Surgeon Guy's Hospital, etc. Second Edition. William Wood & Co., New York, 1925. Price, \$2.25.

The fact that this is a second edition of this little

book proves there is some demand for it. This demand is evidently from the laity. It is a book that medical men may place in the hands of their patients to emphasize the importance of abdominal exercise. A few good exercises are described and illustrated with photographs. HENRY F. KRAMER.

DIABETES, ITS TREATMENT BY INSULIN AND DIET. A Handbook for the Patient. By ORLANDO H. PETTY, A.M., M.D., F.A.C.P., and WILLIAM H. STONER, A.M., M.D., F.A.C.P. Illustrations and Tables. F. A. Davis Co., Phila., Pa., 1925. Price, \$1.50 net.

Doctors Stoner and Petty present another handbook or manual for diabetics, and address their small volume to the patient. Nearly half of the volume is given over to a discussion of the cause, prevention and diagnosis of diabetes, and a chapter on foods in general, including tables showing the vitamin content of the various foods. The last half of the volume, which treats of the weighing and measuring of foods, and the methods of estimating diets, with tables of food values and rules for cooking these foods, far outweighs the first in value to the patient. They present a scheme for calculating diet which is original and well adapted to the average patient's training and mentality. Particularly of value is a specimen daily blank, which can be filled out for each meal and this will simplify the calculation considerably. There are also chapters on the use of insulin, rules for injection, examination of urine, and hygiene of the diabetic. The authors do not propose to supplant the physician by this handbook, and they have given the bulk of the material which is useful to the patient. It should be of definite service to physicians, in their own hands or on the shelves of the reference books of their diabetic patients. L. C. J.

SELECTED ESSAYS ON ORTHOPEDIC SURGERY. From the writing of NEWTON MELMAN SHAFFER, M.D. (University of the City of New York, 1867), F.A.C.S. Illustrated. G. P. Putnam's Sons, New York and London, 1923.

This volume is a collection of the most important papers published and lectures delivered by the author during his active career. Some of the writings appeared as early as 1877 and some as late as 1901.

The papers on tuberculosis of joints, although written before the discovery of the tubercle bacillus, give an exposition of the subject which holds just as true today as when they were written. The article on reflex muscular contraction in joint disease is a classic and may be read with benefit by all interested in the subject. The principles of the mechanical treatment of joint tuberculosis are clearly set forth. Some of the appliances described should receive greater consideration. His knowledge of mechanical principles and skill in their application is rare.

One section takes up "Club-foot, flat foot, and non-deforming club-foot." He uses the latter term for what we now call contracted or claw-foot. This is an original work and well taken up.

Some of the other more important papers deal with the traction and abduction treatment of ununited fracture of the neck of the femur, the treatment of acute and sub-acute inflammation of the knee joint permitting locomotion, and the hysterical element in orthopedic surgery.

Although there is nothing new in this work, some fundamental orthopedic principles are so clearly brought out that it will make interesting and instructive reading for those interested in the subject.

J. B. L'EPISCOP

the lesser buying activity of New York doctors is due, in part at least, to the availability of two great medical libraries in Greater New York, and the consequent lessened need for large private libraries. Still, one exhibitor was inclined to the opinion that the Western doctors were habitual readers of medical literature.

Publicity The subject of Medical Publicity was frequently mentioned by the officers and speakers, and physicians as individuals were urged to instruct their patients in the fundamental basis of medicine,—how an antitoxin works, the contagiousness of "colds," and the reasons for an early operation in cancer. The officers set a consistent example to the individual members by giving information to the reporters of the newspapers and the Associated Press. It was the pleasant duty of the Executive Editor to act as guide to the reporters, to explain the actions of the House of Delegates, and to introduce them to leading physicians who would explain medical points of popular interest. The reporters were on the watch for the strange, the wonderful, and the new, but withal they were after the truth,

and in no instance did they stretch a fact to magnify it into a sensation. The proceedings were surprisingly free from sensationalism, and even threatened disputes in the House of Delegates lost their news value, as they were referred to the Council for study and investigation.

Newspaper men have hitherto complained of the reticence of physicians, and of their lack of unanimity. The reporters of this State meeting expressed their gratification at the frankness of the doctors and their unanimity in essential matters.

Newspaper space given to a subject depends on several factors. The leading dailies of New York City kept their reporters in almost continual attendance at the meeting, but the desk editors used only about one-third column in each issue, for the meeting of the State Medical Society was only one of many important events that were taking place throughout the world. Doctors may well be gratified that their meeting was considered to be of sufficient public importance to justify the constant presence of high-class reporters, and of space in the news columns.

THE ANNIVERSARY MEETING

The Anniversary Meeting of the Medical Society of the State of New York, held in accordance with the provisions of the original charter granted by the Legislature, was held on Wednesday evening in the Grand Ball Room of the Hotel Waldorf-Astoria, New York City. Dr. Edward R. Cuniffe, Chairman of the Committee on Arrangements, opened the meeting and, before introducing the President, he announced that the general subject of the evening would be the Prevention of Diphtheria. He said that when doctors see an opportunity for service, they give up pleasure and devote themselves to serious work. The medical profession has sufficient knowledge and means to stamp out diphtheria, but the knowledge is not effective until it has penetrated not only to the doctors in every hamlet, but also to the people so that they will accept the procedure. Marvellous cures are claimed by quacks, but only doctors can prevent diseases.

The first speaker was Dr. N. B. Van Etten, who gave the Annual Presidential address which is printed on page 343 of this issue of the JOURNAL.

Dr. Wendell C. Phillips, President-Elect of the American Medical Association and Past-President of the State Society, gave a brief address on educating the public in medical subjects. He said that the 150,000 doctors who practice in the Nation should constitute themselves teachers in the great Public Health University whose students are the people, and should give informal courses in public health, sanitation,

and medicine. The text books could be the newspapers, and already their editors are asking the doctors to supply the readers with information on health. Few persons are in exuberant health, but all wish to be well, and are seeking the means to attain vigor and strength. Dr. Phillips said that the American Medical Association approved the plan that doctors should do publicity work in instructing the people in public health topics.

Dr. Matthias Nicoll, Jr., Health Commissioner of the State of New York, spoke on the campaign for the eradication of diphtheria in New York State. His first close contact with the disease was made in 1896 and has continued up to the present time. He recalled the helplessness of physicians in treating diphtheria in the pre-antitoxin days, especially laryngeal cases from which, in hospital practice when tracheotomy had been performed in order to keep the children from choking to death, there were very few recoveries. With the practice of intubation, perfected by Dr. Joseph O'Dwyer, one-third of the cases recovered, and subsequently when antitoxin was made available, two-thirds of the cases recovered. He recalled the first antitoxin, which was pretty poor stuff and said that what it lacked in potency was made up in its power to produce every variety of serum sickness. Following the general use of antitoxin as a preventive and cure, the death rate from diphtheria fell enormously, but as time went on, the number of cases showed little diminution and even a tendency to mount. It has

a month, more scientific papers will be needed. The Editors hope to make out a schedule for the publication of papers, and to supplement them with other papers which shall round out the topics into a more complete form.

The Scientific Committee had chosen program subjects which appealed to the average physician, and their success was shown by the fact that the meeting rooms were well-filled, although they were of unusual capacity. As examples of the practical nature of the programs may be cited the discussion of the newer phases of scarlet fever diagnosis, treatment and prevention at a joint session of the sections on pediatrics and of public health, the discussion of the abnormal child by the sections of neurology and public health, and that on vitamins in the joint meeting of the sections on Medicine, Pediatrics, Public Health. The recognition of the broad relation of one specialty to other branches of medicine was well recognized by the program makers.

The Syphilis Exhibit The last day of the meeting was devoted to a demonstration of all phases of syphilis. The central plan was that of an exhibit covering all phases of the subject,—scientific, clinical, laboratory, and official. The subjects were grouped in sixteen divisions in twenty-eight section booths which occupied the entire floor of the ball room. Cases and pathological specimens were shown in at least twelve sections, and the clinicians and pathologists in charge conducted a continuous series of talks for over three hours. The amount of material that was exhibited was surprisingly large and varied, and was drawn from the abundant material in the laboratories and hospitals of New York City and from the material at the disposal of the Departments of Health of the City and State. The assemblage of the material and of the lecturers and demonstrators was the result of the earnest efforts of Dr. Louis I. Harris, Commissioner of Health of New York City.

The only serious difficulty encountered in the exhibits was lack of room for those who wished to see and hear. At one time in the morning there were over two hundred physicians in the room by actual count, and many more were in the lecture rooms where slides and moving pictures were shown. The attendance was well over five hundred.

The afternoon was devoted to a series of lectures on syphilis, and here, too, the meeting room was crowded.

It is the expectation of the Editors to collect abstracts of the extemporaneous talks that were given in the booths and to publish them in a special number of the JOURNAL, together with the prepared papers that were presented in the afternoon session.

It was the opinion of those who knew, that the exhibit was the largest and most practical that has ever been brought together. Its success prob-

ably assures the collection of a similar exhibit on some general subject at every meeting of the State Society. The subject of cancer is suggested for next year.

The Commercial Exhibits Exhibitors of commercial products showed their wares in the commercial exhibit. Both the visiting doctors and the exhibitors had two objects in view,—one scientific, and one business.

To the doctors the commercial exhibits were almost as interesting and important scientifically as the scientific sessions themselves. They wished to see the latest forms and ^{by} WILLIAM L. WATSON, electrocardiograph, ^{and} Illustrations and 1 of projecting pictures, ^{Price, \$1} modern developments in foods and drinks and drug and the latest editions of books. Here the demonstration could be consulted and new acquaintances formed with the members of firms with whom doctors wish to do business. The tools with which a doctor works and the methods of their use are equally important with his equipment of theoretical knowledge.

The exhibits also enabled doctors to gain business knowledge. The physician puts business in the background when he attends a meeting of a medical society, and yet his living depends on his collections and expenditures just as does the prosperity of the exhibiting firms. The physician will welcome the visiting salesman the more warmly because of the acquaintance formed at the commercial exhibits.

The exhibitors expressed themselves as well pleased. They said that the doctors had shown the expected degree of interest in the exhibits, and had been eager listeners to the demonstrations.

Some exhibitors had emphasized the business side of their demonstration and said that they had taken orders sufficient to pay for the exhibits. Others said they had not reckoned the orders, but had stressed the scientific and social side of their business. One exhibitor who was in a far corner apart from the natural stream of doctors, said that 150 doctors had registered their names at his booth, but when he was congratulated that one-eighth of those in attendance had shown sufficient interest in his wares to write their names and addresses, he replied that last year at Syracuse when he had a booth in the front line where all the doctors passed and many lingered, five hundred had registered with him.

It was enlightening to hear the comments of the exhibitors on the buying instincts of the doctors of New York State. It seemed to be the opinion of book men and instrument makers that the doctors of the Middle West showed buying activities to a far greater degree than those in New York State. This is reflected in the advertising pages of the medical journals of the two sections. As a concrete example the subject of medical books may be mentioned. It may be that

ing the standard of the practice of medicine of doctors throughout the State up to that of the best practitioners

Dr Van Etten also spoke of the common aims and mutual helpfulness of physicians and lay workers in public health. The lay organizations had found that while they could do social and welfare work, they could not hire doctors to do the most effective kind of public health work, for that can be done only by doctors who are in close touch with families and individuals. But while doctors cannot be hired, they may be inspired to do the medical part of public health work, if the lay organizations will do the social service part of the work.

Mr Homer Folks, Secretary of the State Charities Aid Association, which he said was the only State-wide lay organization engaged in public health, gave a frank address in which the relation of the lay health organizations to medical practice was definitely outlined. He said that until some ten years ago there seemed to be a clear distinction between health activities and medical practice, and no serious problem of adjustment seemed to have arisen. During and immediately after the War, however, the field of health activities, public and private, seemed to have considerably extended and the question of adjustment of health activities to medical practice became acute. There ensued a period of criticism and recrimination. The health workers came to see that while certain community health activities did not involve the practicing physician, such, for instance, as the securing of pure water supply, most health campaigns do necessarily involve diagnosis, treatment, and guidance of individuals by physicians. It had also become clear that so far as they are qualified to give the kinds of diagnosis, treatment, and guidance required, the family physicians are by far the best persons to do it. Quite recently, and very informally, representatives of medical practice and of health activities, public and private, had sat down together on several different occasions to work out in some detail just how the family physician and the general practitioners can participate effectively in all the varied health activities that need to be undertaken. These conferences had served the extremely useful purpose of showing that when narrowed down to questions of fact, there is little or no difference of opinion between practicing physicians and lay health workers.

The health organizations are more than glad to recognize the family doctor as the accredited agent for giving medical treatment so far as the medical profession was willing to assume the responsibility. As evidence of the new attitude, Mr Folks mentioned the active support of the Practice of Medicine Act by the State Charities Aid Association and its subsidiary county organizations, and the harmonious campaign for the

eradication of diphtheria by the administration of toxin-antitoxin by family doctors to children of pre-school age.

The effect of the announcement of Mr Folks will be far-reaching. On the one hand it will suppress the spectre of State medicine with the threat of political control over the doctors, and on the other hand it will mean that the lay organizations and their nurses and other employees will educate the people to trust and patronize their doctors. It means the centering of public health measures in the medical profession, and the relegation of medical duties, so far as possible, to family physicians. It will help to bring about the ideal expressed by Dr George E Vincent at the 1925 Annual Meeting—"Every Doctor a Health Officer."

Dr Wendell C Phillips, Past President of the Medical Society of the State of New York, and President-Elect of the American Medical Association, the National body of which the New York State Society is a component part, spoke in detail of the work of the National Society in standardizing the practice of medicine, and in promoting the medical education of the people according to the measure of their ability to grasp medical truths, which Dr Phillips said was greater than is usually supposed. He made a strong plea for the examination of presumably well persons, and said that the people are accepting and even demanding the examinations. Dr Phillips also paid a high tribute to Governor Alfred E. Smith for his active stand for the support and promotion of Legislation to uphold a high standard of the practice of medicine.

Dr Elmer E Brown, Chancellor of the New York University, spoke at some length on the altruistic services of physicians in promoting public health and thereby diminishing the number of cases on whom their livelihood depended. This is one great reason why the public owes a great debt to the medical profession.

The doctor is like a young factory hand who lost job after job because in each he destroyed the need for himself by inventing a machine to do the hard hand work for which he was hired, but in the end he won the good will of his fellow laborers and a partnership in the company.

Dr Brown paid a tribute to the practicing physicians who while fighting disease, profit by their failures as by their successes and show the spirit of the verses in "The Fire Bringer," by William Vaughn Moody

Of wounds and sore defeat
I made my battle stay,
Winged sandals for my feet
I wove of my delay,
Of weariness and fear
I made my shouting spear,
Of loss, and doubt, and dread,
And swift oncoming doom
I made a helmet for my head
And a floating plume.

long been apparent, therefore, that in order to reduce to a minimum or even to eradicate diphtheria, it was necessary to have some agent which would not only serve as a cure for cases of diphtheria and for the establishment of a temporary immunity, as we have had for many years in antitoxin, but an agent which would confer long or even permanent immunity, especially at that period of life in which there is the greatest susceptibility to the disease and so many fatalities. This agent is now available in form of toxin-antitoxin.

It has been demonstrated that its extensive use in selected areas, as in the City of Auburn and in the City of New York, will greatly diminish the incidence of diphtheria, and there can be no question that if even a majority of susceptible individuals, especially those in the pre-school age, are immunized, the disease will become a rarity.

Dr Nicoll said that he was, at first, rather skeptical as to the advisability of adopting the slogan for the campaign of "No Diphtheria by 1930" and his skepticism was largely based on the belief that the medical profession at large, upon which the success of this campaign must depend, would be reluctant to take an active part in it. The events of the last few months have served to dispel that doubt. The physicians throughout this state, through their county societies and individually, are taking a very great interest and are helping in every way possible, and the assurance contained in the address of Dr Van Etten will be vastly cheering to all those who are endeavoring to make this campaign a real success. The cooperation between organized medical practitioners of this state and the state authorities is immensely gratifying. With it, the progress that can be made in the preservation of health and saving of life is limitless. He trusted that no such misunderstandings, as have existed in the

past between practitioners and health officials of the state, may again arise.

It must be understood that the campaign for the eradication of diphtheria, while it is stated as being of five years' duration, is not for a limited period but for all time. The population must be kept immune and protected from exposure from carriers and the few cases that may arise. If the time comes, as it should, when the occurrence of a small outbreak of diphtheria in the state is regarded as a real menace to the public health, the public health authorities should be given specific power to take whatever action is necessary, as they now have in the case of smallpox.

Dr Nicoll stated facetiously that he wished Dr Harris, Commissioner of Health of the City of New York, would keep his "menagerie" of cultists at home and not permit them to invade the rest of the state.

Dr Louis I Harris, Commissioner of Health of the City of New York, gave figures to show that the number of diphtheria cases in New York City had been cut in half since 1919, and the deaths to one third. He quoted figures to show the prevalence of the disease and the deaths in the days before antitoxin, and said that if chiropractors and other cultists were treating diphtheria cases, the present death rate would be increased ten times.

Dr Harris said that it was poor psychology to set an impractical goal, such as that of "no diphtheria in 1930," but the present striking reduction in the number of cases and deaths would be far exceeded when it became the universal practice of physicians to immunize the young children of their families.

Dr William H Park, Director of Laboratories of the Department of Health of New York City, was the last speaker. He said that the subject that was assigned to him was "Debatable Points Regarding the Schuck Test." His paper is printed in full on page 347 of this issue.

THE ANNUAL BANQUET

The period of after-dinner speaking at the Annual Banquet of the Medical Society of the State of New York is the time when doctors preach—seriously or humorously—and thereby unconsciously and often unintentionally reveal their creed or attitude toward other persons and organizations. The Annual Dinner belongs to the President, and his speech and those of the speakers whom he chooses reflects his creed as it has developed or been modified during his year of office. In revealing his own attitude at the Annual Dinner on the evening of Tuesday, March 30th, President Van Etten also expressed the beliefs and aspirations of the members of the State Medical Society. The speakers were chosen as the spokesmen of the American Medical Associa-

tion which expresses the standards and ideals of the physicians of the Nation, of the organized educational forces especially the scientific schools, and of the lay organizations whose object is to rouse the people to a sense of their obligation in public health.

Dr Van Etten in his own address described the important work of the State Medical Society in taking post graduate education to doctors in their home towns, and in giving them basic instruction in modern discoveries and measures which have developed since their graduation from the medical school. Volunteer doctors, qualified as teachers, had been willing to go out to the doctors and give the required instruction. In this way the State Medical Society was bring-

concentrating our mind on syphilis, but in the midst of a thrilling demonstration our guide would introduce us to a president or a chairman or other notable, as if the leaders in the State Medical Society were on exhibition. We also got the impression that we too were on exhibition—all of which distracted us from the serious

business of absorbing the lessons of the syphilis exhibition. We students always have the specter of examinations before us and are urged to concentrate our minds on the subject that is under demonstration. We took our invitation to the exhibit seriously, and wished to make the most of it.

PAST PRESIDENTS' MEETING

A luncheon meeting of the Past Presidents of the Medical Society of the State of New York was held on Tuesday noon, March 30, in the Union League Club, 1 East 39th Street, New York, on the invitation and as the guests of Dr. O. S. Wightman. Those present were as follows:

1894—Dr. George H. Fox
1910—Dr. Charles Stover
1911—Dr. Wendell C. Phillips
1913—Dr. William Francis Campbell
1916—Dr. Martin B. Tinker
1917—Dr. Alexander Lambert
1918—Dr. Thomas H. Halsted
1919—Dr. Grant C. Madill
1920—Dr. J. Richard Kevin
1921—Dr. James F. Rooney
1922—Dr. Arthur W. Booth
1923—Dr. Orrin Sage Wightman
1924—Dr. Owen E. Jones

There were also present Dr. E. L. Hunt, Past Secretary and Dr. D. S. Dougherty, Secretary.

Dr. George M. Fisher, incoming President.

Dr. Lucius F. Donohoe, President of the Medical Society of New Jersey and Dr. J. Bentley Squires of New York City.

The living Past Presidents who were unable to be present are as follows:

1885—Dr. Albert Vander Veer
1892—Dr. Lewis S. Pilcher
1907—Dr. Frederic C. Curtis
1908—Dr. Arthur G. Root
1909—Dr. Charles G. Stockton

The Dean of those present was Dr. George H. Fox, who was President during the year 1894. Dr. Fox recalled the experiences of thirty-two years ago when doctors were individualists, and medicine was curative only. Very few physicians gave thought to preventive medicine, and medical societies confined themselves to the reading of scientific papers.

One who was familiar with the early beginning of the practice of civic medicine and of the activities of medical societies in public health, is amazed at the progress that has been made

and at the ready acceptance of civic duties by physicians, yet the present day activities of the medical societies of the State and the several counties was the result of the self-sacrificing work of a few leaders who had vision of what the public expected of the doctor and a broad outlook on the progress to come in the sciences of medicine and sociology.

Dr. Wendell C. Phillips, President during the year 1911 and President Elect of the American Medical Association, expressed the greetings of the Medical Society and spoke of the policy of the American Medical Association in emphasizing the role of the doctor in the preventive phases of the practice of medicine. He reverted to what is now entirely past history and explained some misunderstood points regarding compulsory health insurance which at one time seemed on the verge of adoption. In those days it seemed wise to get the best terms possible for the doctors, and some leaders felt that if the doctors of New York State would dictate how compulsory health insurance should be carried on, the position of the profession would be much stronger than it would be if the doctors acted entirely on the defensive.

Dr. N. B. Van Etten, retiring President, said that an outstanding medical event of the year was the understanding between the medical societies and the lay health organizations regarding their respective views of work and that now the two groups of organizations were working together with harmony and efficiency.

Dr. George M. Fisher, the incoming President, said that, after his long experience in the inner circles of workers in the State Society, he entertained no illusions regarding the work and time required in filling his new office, but he had arranged his business affairs so that he could give whatever time was necessary to the discharge of the presidential duties.

The meeting of the "Elder Statesmen" of the Society was so full of possibilities for usefulness that it will probably be made a feature of every Annual Meeting of the State Medical Society.

From the shutting must of death,
 From the failure of the breath,
 I made a battle-horn blow
 Across the vales of overthrow
 O hearken, love the battle-horn!
 The triumph clear, the silver scorn!
 O hearken where the echoes bring,
 Down the gray disastrous morn,
 Laughter and rallying.

Dr Brown said that if the doctors were decreasing the demand for their curative services, they were just entering upon a greater field of education, which included physical examinations before the development of disabling disease, the acceptance of instruction regarding diet and hours of labor and rest, and a multitude of other subjects in preventive medicine to which people now

give heed only when they are visibly threatened with pain or sickness

Mr Lloyd P Stryker, Counsel of the State Medical Society as plaintiff, made an impassioned plea that the jury of doctors would support the Practice of Medicine Bill

Dr George M Fisher, the incoming President of the Medical Society of the State of New York, made a brief inaugural address in which he expressed the hope to carry on the forward-looking policies of the present administration

Dr Edward R Cuniffe, Chairman of the Committee on Arrangements, presided, and made a happy impression by his brief and pointed introductions of the speakers

THE SYPHILIS EXHIBIT

By A MEDICAL STUDENT

The demonstration of syphilis in the State Medical Society was inspiring to a medical student. Although in his college courses he was "fed up" on collection of museum specimens and surfeited with more cases than he could digest, the end of a three hour inspection of the ensemble of specimens, cases, charts, lectures and demonstrations found his appetite for knowledge as keen as at the beginning. The reason was that the exhibit was more than impersonal encyclopedia, it visualized and humanized the subject as it showed persons affected with a disease to which its victim was a side issue. The human point of view was rather novel to the medical student who was accustomed to look at only the scientific aspect of syphilis. The demonstration would be deeply appreciated in any medical school as a means of teaching syphilis to a body of students

We are gratified to find the leading syphilographers of New York demonstrating in the several cubicles and were reassured by their willingness to impart instruction of an elemental nature such as students needed and which the practicing physicians also seemed to relish

While the motion pictures and charts were self-explanatory, the patients who were demonstrated by competent men impressed us most. A patient who exhibits himself and permits himself to be examined is worthy of recognition as an essential part of the teaching faculty

Lack of time and the pushing of eager listeners behind us compelled us to give only five minutes to each of several demonstrations to which a whole hour could well be devoted in the medical school, but in that brief period we got a visualization of the subjects and an inspiration which will be an incentive to further study at the medical school

Despite the superficiality with which the time-pressed student was forced to hasten through the demonstration, certain exhibits were outstanding in their impressiveness. It was a privilege, for example, to view patients with pulmonary and gastric syphilis which the medical school professors have repeatedly termed as extremely rare and therefore have passed over in lecturing with no more than mention of their possible occurrence. The same was true of syphilis of the eye and ear and tended to impress the infinite pains which had been exercised to make the exhibit complete in minor details

The experimental work on syphilis was a profoundly interesting exhibit, and was perhaps the one requiring the most time to impart the maximum amount of knowledge to the student who was utterly unacquainted with what had been done in the inoculation of rabbits with syphilis

The serological diagnosis syphilis was adequately rehearsed by an actual laboratory demonstration of the Wassermann test and the Kahn test. The latter was a novelty to us

A certain exhibit was spectacular from the viewpoint of the morbidly curious, but it was also a gratifying demonstration of what other agencies can do good where the best medical knowledge has been baffled. This was the repair of defects which have been left in mouths of syphilitic victims and which have been declared inoperable by surgeons, but which have been benefited by dental appliances. Roof plates were on view which would return power of speech to those who were speechless because of gross defects in the palate and roof of the mouth

In conclusion we wish to add a point in psychology. We had been invited by a physician who impressed upon us the unique opportunity of

PRESIDENT'S ADDRESS

By N B VAN ETTE, M D, NEW YORK

The Minutes of the Annual Meeting of the Medical Society of the State of New York, March 31, 1926

Philosophize as we may, none of us are able to step out of the procession in which we are marching, to obtain a viewpoint of sufficient perspective value to estimate the progress of our own time, or gain a reliable vision of where we are going. We are quite impressed with our own importance and prone to forget that we started our careers from foundations erected by our immediate predecessors, and that those who succeed us will be helped or hindered by the measure of our accomplishment.

A proper application of precedent to prediction may perhaps be obtained by going back a little, and so I am going to try to relate the high lights of the story of a doctor of our preceding generation.

Graduated from the Albany Medical College in 1853 he entered country practice, where a contemporary speaker says only good doctors succeed, served through the Civil War as regimental and brigade surgeon, operating in front-line service, built a smallpox hospital, cleaned up an infected city, literally white-washed it with the assistance of squads of negroes pressed into service, observed the horrors of unclean military field surgery, as recorded in the History of the War of the Rebellion, finished the service with the rank of colonel, resumed practice in the country, the town having become a railway terminal, he became the railroad surgeon, when accidents were of daily occurrence, became a master of traumatic surgery, greatly worried by infections, developed a technique and secured results approaching those of today, by practicing intensive personal cleanliness, using instruments immersed in boiling water, almost boiling his own hands in those days, before the knowledge of bichloride or the rubber glove, applying dressings wrung out of boiling water so hot that they almost cooked the tissues, not realizing that he was almost practicing modern aseptic surgery, meanwhile carrying on a large general practice, driving night and day, in rain and snow, in every season, the best and fastest horses he could buy. Answering cheerfully every demand regardless of remuneration, doing emergency life-saving operations in any farm house with no assistance, giving an anæsthetic and operating at the same time, taxing his ingenuity to meet unexpected situations far from the cities from whence he might have called expert help. Having no nurses except members of the household, often dangerously inept, spending many hours with children choking to death with diphtheria, swabbing throats at risk of his life, doing emergency tracheotomies and losing the battles be-

cause he had no specific remedy, reading omnivorously current medical literature, interested in local community conditions, not an office holder, but a party leader, respected because of his judgment based upon attainment, an interested leader in medical organizations, he possessed the love of many people and died in 1894 at the height of his career, after 41 years of continuously active practice of his profession with a vision of our modern medicine just opening out before him.

An inscription seen upon a tablet in a church recently fittingly described him: "In him a venerable aspect and dignified manners were united with a strong and sagacious mind stored with the treasures of ancient and modern learning."

He was the finest type of general practitioner of the last generation.

The doctor of the last thirty years has seen remarkable development of surgical technique, a development of diagnosis based upon bacterial investigation, a better understanding of disease transmission and of methods of epidemic control, treatment of disease progressively less empirical and development of methods of disease prevention that have scientific foundation and proven value that encourage us to believe that many other enemies of the human organism may be defeated by specific remedies.

For the prevention of typhoid fever, tetanus, smallpox and diphtheria we have specific vaccines so reliable that those who know about them and fail to use them are morally culpable.

In my opinion this statement is quite as applicable to the lay people who know, as to the physicians who know. It is a national disgrace that we had more than 4,000 cases of smallpox in the United States in one month of last year, with a total of 31,037 for the year. It is a national disgrace that our people care so much more for matters of convenience than for the protection of the lives of their children, that they care so much for what they are pleased to call personal liberty, that they are willing to expose their fellow citizens to the potential ravages of a loathsome disease. It is with no feeling of pride that we compare the record of that month with 4,000 cases of smallpox, with the record of no cases of smallpox in that same month among the disciplined and vaccinated citizens of Germany.

In the light of the truth of this statement one easily sympathizes with the pessimism of many at the beginning of any public health campaign. Toxin-antitoxin as a preventive of diphtheria has been known ten years and yet

SECRETARIES' MEETING

A luncheon meeting of the Secretaries of the County Medical Societies was held at one o'clock on Wednesday, March 31st, in the Waldorf-Astoria Hotel with the following present

From the State Society

N B Van Etten	President
W H Ross	First Vice President
G M Fisher	Incoming President
J S Lawrence	Executive Officer
Frank Overton	Executive Editor

From the County Societies

W H Betts	Westchester
E P Kolb	Suffolk
A D Jacques	Nassau
L F Schiff	Clinton
E Bieber	Chautauqua
S W Sayer	St Lawrence
F J Schnell	Niagara
J P Henry	Monroe
H A Peck	Albany
F H Voss	Ulster
J A Lichty	Ontario
E E Smith	Queens
I J Landsman	Bronx
D S Dougherty	New York
W W Britt	Erie
J D Carroll	Rensselaer
T M Brennan and W Ludlum	Kings

Dr Harrison Betts, who was elected President of the Secretaries organization last year, presided

Dr I J Landsman said that the Bronx County Medical Society is putting on post graduate courses patterned after those of Kings County. He also described the promotion of periodic health examinations by the distribution of form cards with considerable success. One doctor had examined three hundred patients during the last year and other doctors were entering into the work.

Dr J P Henry told of the relations of the Monroe County Society to civic organizations, such as the Chamber of Commerce. He said that the lay organizations were beginning to go to the County Society for advice and were willing to let the doctors arrange to do the professional work in their own way, while the laymen did the administration work that was necessary in order that the doctors may work effectively and with satisfaction to themselves and the patients.

Dr G M Fisher, incoming President of the State Society, asked the doctors to adopt business methods in filing and answering letters. He suggested that each Secretary could at least have a letter file in which he could keep his correspondence where he could find it.

Dr, W W Britt, Chairman of the Committee on Economics of the State Society, told how he had gone to the county societies of the Eighth District Branch and got them to sponsor the Health Examination program.

Dr Van Etten, President of the State Society,

told of his observations of the meetings of the District Branches and suggested a greater development of the social side of the organization. He quoted the meeting of the Third District Branch as the best one for sociability and acquaintances. It lasted two days, and many wives of the members were present and added to the enjoyment and good fellowship of the meeting.

Dr D S. Dougherty, Secretary of the Medical Society of the State of New York, and also of the New York County Society with 3,500 members, gave an outline of the history of the development of the present organization of the State Society and urged the County Secretaries to adopt business methods in the conduct of their offices, and especially to answer letters promptly.

Dr T M Brennan, Secretary of the Kings County Society, read a paper in which he outlined the activities of the Society, especially in civic lines.

Among the activities of his Society, he mentioned the following:

1 The promotion of intensive courses in medicine and surgery jointly with Long Island College Hospital Medical School.

2 The management of the Friday Afternoon Lectures on the more popular medical topics.

3 The consideration of civic topics at the monthly meeting of the Society at which laymen were invited, such as the Police Commissioner and the President of the Chamber of Commerce.

4 The prosecution of illegal practitioners.

5 The promotion of periodic health examinations along original lines.

6 The preparation of leaflets on various phases of disease management.

7 Studies into the cost of sickness.

8 Co-operation with the other county societies in Greater New York in the study of civic problems.

Dr Brennan promised to expand his paper for publication in this JOURNAL.

Dr W H Ross, a member of the newly established Board of Trustees of the State Society spoke of the acceptance of money from laymen and lay organizations for carrying on the work of the Society and said it was already being done in the counties of Kings, New York, and Suffolk, and no one had criticized it.

Plans were discussed for a general meeting of the Secretaries to be held in the early fall, preferably in connection with the annual conference of Health Officers in Saratoga Springs. On motion it was voted to request the Council to authorize the meeting.

It was the consensus of opinion that meetings of the Secretaries of the counties of the District Branches should be held in connection with the District Branch meetings.

The discussions lasted for two hours and all those present considered the secretaries' meetings to be well worth promoting.

meetings every two weeks. First dissecting the old law, and then adjusting collected opinions, it evolved a new medical practice act, which was approved by the Council and published in the November JOURNAL.

An essential amendment carrying annual re-registration resulted from frequent conferences with the Department of Education and with Legislators and State Officials concerned with public health administration. The chairmen of County Society Legislative Committees met and agreed that the act was in the interest of the public health, and voted to support it, but when the bill was discussed in meetings of the County Societies, many physicians exhibited absolute ignorance of the measure, had not read it in the Journal, and expressed surprise that they had not been individually consulted. Meanwhile the measure had attracted the favorable attention and engaged the active support of lay organizations interested in the advancement of the public health through the employment of persons qualified by education for the care of the sick, and largely by their help the bill will probably pass both houses of the legislature, and receive the approval of the Governor.

A study of the attendance at Medical Meetings reflects the interest of many physicians. The presentation of a new scientific observation or a new exposition or new light upon an old subject or a symposium participated in by well-known observers of a well-worn but frequently met pathological subject will attract large audiences, but a meeting for the special consideration, of economic questions vitally affecting the physicians' welfare, or even affecting the physical welfare of the public, will be slenderly attended. The relation of many physicians to constructive medical legislation, or even to defensive legislation against the quackery or folly of those who intentionally or mistakenly try to destroy the confidence of our citizens in well-established scientific truth, is very much the relation of large numbers of our citizens who ignore their civic responsibilities by failing to take an interest in primary politics, or even if the exercise of the franchise in the selection of their representatives. In the presence of such an exhibition of self-indulgence, one can not honestly credit such physicians or such citizens with altruistic inclinations.

"Which would you rather be, a cup to be drained, or a measure to be filled?" The doctor of the future will answer that question in the same manner as doctors have always answered it but there will be more satisfaction and potency to draw from him than ever before. His education will keep better step with the progress of preventive medicine, and with a clearer popular understanding, with a brush-

ing aside of the mysteries of medicine, people will follow his well-defined leadership toward the goal of health efficiency.

We neither need nor desire a less competent physician, the curriculum will be adjusted to meet the changing order. I would rather lengthen it than shorten it, but I would not terminate it later. I would add a year or two at the beginning of the course and make his ancillary education more definitely medical. I would broaden his vision by showing him the history of medicine, and I would improve his manners by a real course in medical and social ethics. I would teach him anthropology. I would have him taught methods of complete investigation, so that no subjective symptom should be dismissed without attention. I would have him study physiotherapy so that he would be able to appraise its value. I would require of him a period of the general practice of medicine so that he might acquire broad fundamental knowledge before he should be permitted to enter a post graduate school to qualify himself for specialized endeavor.

Every doctor needs post graduate education every year, and most of them feel that they are unable to leave their active work to take courses within the walls of teaching institutions. They may be able to attend meetings of medical societies where they usually listen to ultra scientific discussions which are often unintelligible except to a few advanced students, most readers thinking that unless they present rare cases their work will not attract attention.

The great majority of physicians desire what Osler used to call brain dusting, and need refreshing of their knowledge just a little beyond the work given to the fourth-year medical student. We have offered during the last year post graduate education to the doctor in the vicinity of his home. Courses in obstetrics, gynecology, pediatrics, cardiology and tuberculosis have been asked for and given in many counties and have been attended by large numbers of intensely interested physicians. The rapidly increasing demand for this teaching is an index of its complete success.

We have advocated the annual birthday examination of apparently well persons and our eleven thousand members have each received a manual and charts describing and illustrating the details of such examinations. Standardized health is possible. Industry is interested and will require health measurement of applicants for employment. Annual health inventories will be taken and corrective measures will be used to maintain the highest standards of health efficiency. With increasing competition the sick will not be able to maintain the pace set by the healthy and will obviously fall out of line.

the public does not clamor for protection of their children that they pretend to love so dearly. Thirteen thousand of them died from diphtheria last year and there was no excitement about it, 700 died in the City of New York, and there were 10,000 cases here. If 10,000 people had been burned in a fire and 700 of them fatally, the country would have gone into mourning. Is it any less disastrous to have them die from a preventable disease?

In the city of Auburn with 36,000 people, as the result of an intensive four-year campaign, conducted under the direction of Sears, of Syracuse, there have been no deaths from diphtheria in the last two years. Are the children of Auburn more valuable than the children of Buffalo or New York, or have these Auburn people greater intelligence?

Is it possible to arouse opinion to an appreciation of this situation by appealing to affection for children or to the intelligence of interested citizens? Is it possible for the public to realize the handicaps of the 19th century doctor of whom I spoke, and carelessly toss aside the enlightenment and the proven defenses of this 20th century? Will a large number of people continue to close their eyes and ears to honest scientific endeavor and continue to depend upon, rabbits' feet, or horse-chestnuts, or amber beads, or other charms to carry them safely? Is it possible to educate people to stop coughing and expectorating in one another's faces while enjoying the intimacies of New York City transportation?

Shall we be able to teach people the dangers of the common cold, and the facility of its transmission? The involuntary subway intimate who salutes your nostrils with the odor of garlic or other edible perfumery, is much less subtle than the one who sprays the air with colonies of disease germs through unguarded cough or sneeze. Do we often enough, and loudly enough, tell the world that tuberculosis may be transmitted in this manner? Has this last gripe epidemic carried a convincing lesson to a large number of people? Is there any promise of successfully entering the consciousness of the citizens of a great city so that the sense of self-preservation may be aroused?

The intelligent and able citizen carries his family into suburban open country to escape pestilential communication. He arises before dawn to get to his work with the mob at 9 o'clock. He leaves with the mob again at 5 o'clock, and returns to his home after dark, tired by the struggle, but at least conscious that he is trying to develop a healthy family.

The fresh air, open window campaign of the tuberculosis committee several years ago undoubtedly was fruitful. The popularity of out of door sports and Boy Scouts hiking is undoubtedly inspirational in health promotion,

and should help in our campaigns for the employment of specific agents in preventive medicine if we may be able to present them to the public in a forcibly intelligent manner.

A five-year campaign to eliminate diphtheria from the State of New York, with the inspiring cooperation of the State Department of Health, the State Charities Aid Association, the Metropolitan Life Insurance Company, interested philanthropic individuals, the Homoeopathic State Medical Society and the Medical Society of the State of New York, to be carried on through our Public Health Committee, by and through all physicians of the State, has been under way since the first of the year. My correspondence shows that most of the counties of the State are actively interested, and well defined county campaigns are already functioning in Erie, Monroe, Onondaga, Schenectady, and Albany Counties, headed by the County Medical Societies, and enlisting the working interest of local lay organizations.

The goal is possible of attainment and a concurrent enlightening of public opinion, and an awakening of public interest in the prevention of disease may have an inestimable future value.

Public interest in public health is daily dis-closed to those who are studying social conditions. Critical attention, tempered with impatience, is being given to all forms of health service. The layman protests that the nursing situation is intolerable, that the supply does not meet the demand, that the cost is prohibitive, and the service independent. Our Society has been trying to appraise the truth of these complaints, to discover the reason for them, and if possible a remedy for them during the past year, and will continue to study, perhaps beginning with the demand of the bed sick patient, the cost, possibly the distribution of it, and the character and curricular qualifications of nurses. We have already a large mass of informative material.

The Mayor of our greater city finds our greatest hospital inefficient and its psychopathic pavilion a public disgrace. His keen interest in public health is only in part stimulated by physicians.

A year ago pursuant to the order of the House of Delegates, I appointed a Committee to study the laws under which the practice of healing arts is conducted, and to prepare a new medical practice act which would amend the law in accordance with the desires of physicians, and in the interest of the public health. The committee was chosen with the hope of harmonizing opinion within the medical profession, and outstanding representatives of groups known to have exhibited divergent views were appointed. This committee labored diligently from the first of July, holding formal

THE USE OF THE SCHICK TEST BEFORE AND AFTER INJECTION OF TOXIN-ANTITOXIN FOR IMMUNIZATION

WILLIAM H. PARK, M.D.
NEW YORK CITY

The Minutes of the Annual Meeting of the Medical Society of the State of New York, March 31, 1926.

OWING to the different conditions in different localities the use of the Schick test is advisable in some and inadvisable in others. This leads to some confusion in the advice given on the subject. It is evident that the Schick test has nothing to do with immunization. The result of its use simply indicates immunity or not immunity. It is desirable to use the Schick test when considering all the circumstances it aids rather than retards the use of the immunizing injections. The Schick test itself depends on a number of factors as to its successful use. The toxin prepared by the laboratory must be properly standardized and put in suitable glass tubes for its conservation. The physician using the test must be skilled in its use as otherwise the fluid will not be injected in proper amount and into the skin rather than through the skin, he will not be able to decide on a true reaction or a pseudo-reaction but will have to consider all pseudo-reactions as true reactions so as to be on the side of safety. When the toxin is properly prepared and properly given and the test is properly read the Schick test is very dependable. In large cities such as New York, Buffalo, Rochester, and so forth, the majority of the children going to school give a negative Schick test and the use of the test in the schools is believed to help rather than retard the use of the injections. In the first place by relieving the physicians of giving the three injections to those who are immune and again by being able to say to parents that those who are not immune will receive the injections. In small towns and country places the majority of the children are not immune and here it is the wisest custom not to give the preliminary Schick test.

In pre-school children the conditions are different, even in large cities the majority of the children are not immune and in children of these ages not only in the country but in the cities the Schick test is wisely omitted. In those of the boroughs of New York City we avoid the difficulty by giving the toxin-antitoxin in the first injection strictly subcutaneously. This acts both as an immunizing action and as a Schick test.

The use of the Schick tests after immunization stands on a different footing. This should be done wherever possible because with the best results only from 90 to 95 per cent become immune. If a retest is not done we are never quite sure which children are immune and which children are not. In the earlier days of the use of toxin-antitoxin the Schick test was absolutely necessary because it was so important to know

just what percentage of those not immune became immune after the injections and how long this immunity lasted and also whether those who did not become immune would become so after given the second series. It was through the means of the Schick test that we learned that good preparations gave immunity on the average of 90 per cent of the children injected and a second series immunity in most of the remaining 10 per cent and that this immunity lasted in the very great majority for over five years and so far as we know in the large majority for life. We also learned that those who are resistant to one series of injections could in the very great majority of cases be immunized by the second series and that no child was absolutely resistant to immunization.

Harmlessness of the Toxin-Antitoxin Injections—Probably over two million injections of toxin-antitoxin have been given in New York State alone and no accident of any seriousness has happened. In the whole world I know only of three accidents. One, years ago in Dallas, Texas, where through a mistake of toxic preparation was used. This accident led to the biological manufacturing plants adopting, at the suggestion of the Hygienic Laboratory, rules and regulations which must absolutely prevent any such accident happening again. The second was an accident which happened in Vienna last year, which was at first advertised as the result of changes in toxin-antitoxin, that is, a product which was harmless became on standing harmful. Within the last few weeks, however, a communication from Vienna states that it has been shown that through an accident diluted toxin was sent instead of toxin-antitoxin. The third accident which fortunately had no serious results was the use of toxin-antitoxin immediately after thawing the frozen product. The fact that toxin-antitoxin would temporarily become poisonous on thawing the frozen product had not occurred to anyone. It is interesting to note that the new standard preparation of toxin-antitoxin universally used in this country which contains only one-thirtieth of the amount of toxin used in the first preparation is absolutely harmless when used after freezing and thawing.

Toxin-antitoxin produces a moderate amount of local inflammation in two types of cases due to two different substances. Those who have absolutely no immunity show a local reaction through the slight excess of toxin in the toxin-antitoxin mixture. This is of only very moderate severity and lasts only a few days. This is especially apt to occur in young children. In

Physicians will not submit to being grouped in a panel as under a compulsory health insurance scheme and such work must ultimately fail because only the poorest practitioners will engage in it. The highest class doctor will not wear an identification tag as a member of a panel. Public Health Education of all the people will react favorably upon the physician materially if he will take advantage of it, the inspiration of periodic physical examination advice will be valuable to the physician if he will adjust himself to it, not one of those asking his advice are physically perfect, careful study of each one will reveal some condition that requires correction, he will help himself materially and improve his scientific equipment by following the leads that are presented to him. The physician of the future may again become priest, and counsellor as well as doctor. Investigation stimulates interest in the investigated. The field is fertile and largely unplowed. With 770 persons for each doctor in the State of New York to take care of, there is small excuse for idleness. He who tries will find plenty to do, and he who constantly studies will help himself and his community.

Organized medicine in this State has more cooperation than ever before, the Governor has a greater appreciation of health value than any of his predecessors. The State Department of Health sees the development of efficiency in public health to the highest standard through and by the practitioners of the State. Lay organizations, religious organizations, philanthropic individuals, commercial organizations see high efficiency and prosperity and happiness through preventive medicine conducted by and through physicians.

A general appreciation of interdependence of organizations interested in mass welfare seems to prevail. That public health is purchasable, has become a high light in the imagination of those really interested in improving civilized living, and also a realization that money alone will not buy it. While it is perfectly possible to bring up a district to a condition approaching an ideal, by an intensive campaign conducted with lavish expenditure and the whole time employment of doctors, except as a demonstration it has small value, because it can not be sustained efficiently and because momentum will slacken with the withdrawal of the financial drive.

The physician is an individual, his development from birth to diploma has taken twenty-seven years, has cost more time, money, and effort than is required for the development of any other kind of worker. He sees no financially attractive prospect. He sees a sentimental reward in appreciation of his work by the people he serves, a respectable and possibly a comfortable maintenance for his family. His life is full of interesting potentialities. The prospect of service in the field of preventive medicine is alluring, but he can not be hired as a class to effectively render that service. He must be inspired with the value of such work and his own importance to its success.

A campaign in Preventive Medicine, such as one to eliminate Diphtheria can be started by one or more executive organizations, but it can not be carried to successful and lasting conclusion except by the physicians meeting this spirit of cooperation with the warmest reciprocity and the will to put over and maintain a complete victory over a dread disease.

The physicians of this State must awaken and rise to the leadership that is waiting for them not only in the fields of preventive medicine that have been well demonstrated, but in the conflict with enemies that are still surrounded by obscurity, and also in the fight for supremacy over an apparent racial decadence through reckless breeding and the lowering of our moral and physical standards by luxurious living.

The Medical Society of the State of New York is largely representative of the best of the profession. It can do great things if it will accept now those unexampled opportunities for leadership toward the highest ideals with thorough appreciation of the fact that the highest standards of public health can only be attained by and through the efforts of physicians.

With reverence for the honorable traditions of our sires, and with the deepest respect for the intense individualism of physicians, which is an evolutionary result of contact with the real confidential, unmasked conditions of life, where real decisions are made, and where soul and body and history are unreservedly disclosed as inviolate communications, by the grace of education and a broadened and enlivened spirit of service we approach the dawning of a new day in medicine and a new vision of useful leadership.

PHYSICAL AGENTS IN THE TREATMENT OF SOME COMMON DERMATOSES

By ADOLPH ROSTENBERG, M.D.
NEW YORK CITY

REVIEWING the progress in the treatment of skin diseases during the last two decades, we find that physical therapy has by far surpassed the efficacy of drugs in great many cases.

The etiology of the majority of skin diseases, in spite of incessant research work, is still obscure and a matter of speculation and theory.

Hence the only rational therapy, based upon attacking the underlying cause, seemed impossible and the treatment was necessarily more or less symptomatic.

Fortunately, just in this group of cases, physical therapy has proven of very great value.

Of the various physical agents introduced, the X-ray undoubtedly takes the first place, thanks to the perfection of the modern transformer machine and the Coolidge tube, which made it possible, to introduce more simple and accurate methods of measuring the dosage.

Today it is admitted by all leading dermatologists that the X-ray is the most successful single therapeutic agent in dermatological practice. This fact can be easier understood when we come to realize how wide their range of usefulness is, as they are capable, by varying the dosage, of either stimulating or inhibiting or destroying the reproductive property of animal tissues, particularly is this effect shown upon embryologic, secretory and certain groups of abnormal cells which play an important part in the production of inflammatory or neoplastic skin diseases.

This explains why X-ray treatment is so successful in the therapy of all eczemas, which undoubtedly is the most commonly met skin disease, representing an incidence of 60 to 70 per cent of all dermatoses. The pathology of an eczema shows an exudative catharr of the skin, either acute, subacute or chronic, with a hyperplasia and infiltration of cells, and in the chronic type a hyper and parakeratosis in addition.

In the acute type of eczema, better designated as an acute dermatitis, the cause is usually known, especially in the large group of toxic dermatitis, which is produced by the action of an external or internal toxin. Here the removal of the causative factor is naturally the first step, if the dermatitis does not subside with the application of a simple protective and cooling lotion, a few additional small doses of X-ray will usually be of great benefit.

In chronic eczemas, the X-ray acts almost as a specific, in inveterate cases, which will resist all sorts of treatment, lasting for years and reducing the patient to a nervous wreck through their

persistence and intolerable itching, yield to a few units of X-ray, best applied in fractional weekly doses.

The same *modus operandi* is used in lichen planus, its various forms, and in psoriasis, which both in their pathology are inflammatory skin diseases. My personal experience with the X-ray in psoriasis has been extremely gratifying, although my optimism is not generally shared. With the exception of a very small minority, even the most inveterate cases either cleared up entirely or were at least greatly improved after a few treatments. The books still state that psoriasis does not itch as a rule, my experience leads me to believe that just the contrary is the case, and I also feel that the continuous scratching irritates the lesion and prevents to a great extent their clearing up with the use of ointments. The X-ray usually relieves the itching before it clears up the patch. Unfortunately does the X-ray not prevent recurrences any more than any other mode of treatment, only it seems to me that the intervals of freedom are longer, the recurrent attacks do not seem to yield to the X-ray treatment as promptly as the first one, and here a sound of warning is in place, as the patients, who invariably prefer the X-ray to any other treatment, clamor for more and more and are apt to be overtreated with consecutive ill results.

While the X-ray has no direct effect on skin diseases caused by animal parasites, bacteria or fungi by destroying them, indirectly, however, they are also of great value in these cases. This is foremost evidenced in the treatment of ringworm of the scalp in children. Heretofore, a successful cure of this wide-spread disease was well nigh impossible, the unfortunate patients would suffer and infect others, until they reached puberty, when the disease would usually clear up spontaneously. Today all that is necessary is to epilate the scalp in one treatment according to the Kienboeck-Adamson method, after which the affected hair falls out together with the offending organism. The same principle underlies the effectiveness of X-ray treatment in cases of favus and sycosis barbæ.

The treatment of acne vulgaris, before the use of X-ray, was as unsuccessful as in tréna. Now, the Roentgen ray is almost universally used for the cure of this trouble. The rational of this treatment seems self-evident when we remember that the underlying fundamental cause of acne is a hyperfunction of the sebaceous glands combined with a follicular hyperkeratosis, which both will disappear under the inhibiting effect of the X-ray.

These few dermatoses enumerated do not he-

older children and adults we have a reaction due to the tissue reaction to protein substances. These substances produce in some, who are sensitive to them, quite a marked reaction so that they may be incapacitated for work for a day or two. These reactions are absolutely without danger but are quite annoying. Because of these reactions the general immunization of adults is not recommended except after the Schick test and a control so that those who show marked pseudo-reactions may be omitted from the injections or given them in divided amounts.

SENSITIZATION

There is a fear among physicians about giving diphtheria antitoxin as an immunizing injection and about giving toxin-antitoxin because of the serum globulins in the two preparations. So far as immunizing injections of antitoxin are concerned, there is no question that there is a definite sensitization of those who are injected. There is, however, no evidence that this sensitization produces a change which makes later injections of antitoxin or serum dangerous.

I have gathered together some thirty cases in which injections of antitoxin or serum were given some three weeks to six months after the immunizing antitoxin injections. In several of these children there was an immediate reaction with rash and temperature. The rise of temperature in one was four degrees and another two degrees. These rises of temperature were quite transient and in the course of four hours the temperature had returned to normal. With the temperature there was a general urticarial rash which lasted for one or two days. This is what we call an accelerated reaction. The reaction in these children besides being hastened may have been somewhat more severe, but there was no sign of danger and in fact within a few hours the children were absolutely in good condition except for the annoyance of the urticarial rash. So far as sensitization with toxin-antitoxin is concerned, we must remember that the amount of serum globulin given in an injection is very small, the amount is equivalent to about one-three thousandths of a cc of horse serum.

Hooker several years ago showed that persons who had received toxin-antitoxin injections gave a higher percentage of positive skin reactions when tested one year later. In repeating his tests Schroder and I found out that there was indeed a slight increase in the normal percentage of persons who gave a slight skin reaction. None of these reactions, however, were severe such as occurs in occasional cases with or without toxin-antitoxin injections.

I have looked up the records of more than fifty persons given doses of serum or of antitoxic globulin solution who received toxin-antitoxin injections from one to three years previously and compared them with an equal number of children receiving injections of serum who had never received these injections. The results of the comparison were very interesting. Practically the same number of the children reacted in those who had received and in those who had not received toxin-antitoxin previously. There were a few reactions in those who had received toxin-antitoxin which were a little worse than in those which had not received it. Whether this difference was due to the previous injections of toxin-antitoxin or to the peculiarities of the children is uncertain but it probably is fair to consider it as due to the toxin-antitoxin. The difference, however, was so slight in amount as to be negligible so that no one would think of withholding toxin-antitoxin because of it.

There is no question in my mind that the cases described as anaphylaxis by Stewart of Minneapolis were simply examples of ordinary severe serum sickness which had little if anything to do with the previous injection of toxin-antitoxin. I have talked this matter over with Dr. Sears and from his large experience he agrees with me that there was nothing whatever for physicians to worry about in the giving of toxin-antitoxin injections. However true this may be there is a feeling about among some that it would be wise to change from toxin-antitoxin to toxoid. We have for several years used experimentally a toxoid prepared by us with moderately good results. We have also used a preparation of toxoid made by Ramon of Paris with results equally good to those obtained from our toxin-antitoxin and we have now prepared a large amount of toxoid according to the method described by Ramon. We intend to test this out very thoroughly and if the results are equal to toxin-antitoxin, we will probably make the change, but there is absolutely no reason to hurry and it is our idea not to make the change for at least another year. As a rule toxin-antitoxin injections give slightly more reactions in the very young and less reaction in the older children and adults. This is due to the fact that the very young children respond to the slightly under-neutralized toxin while older children respond to the proteus in the toxoid. The toxoid is practically without toxic effect but has about thirty times as much of the broth and culture proteins as the toxin-antitoxin.

mind that the approach to such a study should be definitely based on the promise that the fundamental treatment of the delinquent child should be psychiatric in character. From this viewpoint the child is considered to be what he is and to react as he does by virtue of certain physical, emotional and instinctive factors within him in their relationship to his heredity and environment. He is thought of being in a process of unceasing development, the roots of any transient phase of which reach far back in the scale of his biological development. Obvious as this viewpoint is to those of us concerned with psychiatric problems, the point has not come home so clearly as one would hope to many of the institutional directors. The following brief survey of the situation should make this more apparent.

There are three classes of institutions caring for delinquent children in New York State—those controlled entirely by the State, those maintained in part by public funds and under more or less direct supervision by the State, and institutions whose maintenance and policies are directed by private individuals. In addition to this inspected group there are numerous private homes with quite limited supervision. It is obvious that an institutional system drawn from the various sources just enumerated, must have as many different methods in dealing with delinquent children as there are institutions. No process of standardization can be attained and the average level reached is necessarily low.

Other factors besides lack of suitable supervision operate to prevent the intelligent and scientific study of the child for his resocialization preparatory to re-entrance into the life of the community. Secondary only to standardization is the influence of the penal code—an eye for an eye—that so strongly colors our prison systems and which has subtly permeated throughout the institutions for the care of the wayward child. One need not enter into the various causations that have made this belief so persistent, but one must comment upon the fact that the approach to the problem of delinquency still remains largely physical in character. Miss Margaret Reeves, of the Bureau of Juvenile Delinquency, Russell Sage Foundation, has estimated that in the institutions of which I am now speaking, approximately 25 per cent still employ purely penal methods, 25 per cent have a slight recognition of the mental aspect, 25 per cent fully recognize the psychic elements in the situation but lack the funds to provide suitable facilities for the study of such, and 25 per cent modernized in this respect. I believe Miss Reeves has been generous in her estimations.

A third factor as has just been intimated is the lack of funds, with which to "carry on." This is especially true of the private institution where profit or economy, not service, is the controlling

element. The superintendent, broadminded and thoroughly in accord with modern methods though he may be, is more or less a slave to his budget or to the whims of a board which sees nothing in a new idea but social uplift, sentimentalism, faddism and unnecessary expense.

Even the Judiciary brings its quota of misunderstanding to the problem. The Children's Court, an institution of some two years duration, has had perplexing problems so numerous as to preclude a leisurely and thorough study of what the institutions have to offer in the matter of treatment of the delinquent child. As a result the justice too often assigns the wrong type of child to the wrong institution, and thus the careful classification and study of children within the institution itself becomes increasingly difficult.

This general survey as to some of the most important factors mitigating against a more modern approach in the treatment of the delinquent child has not acquired a plaintive tone, I trust, nor has conveyed the impression that psychiatric methods in children's institutions is the panacea for all its troubles. It is only a help at best, a stethoscope with which to probe for the seat of the trouble and to leave to a more highly developed curative technique which the future will doubtless bring forth. Enough has been said, however, to lay the ground work for the more detailed discussion of the several institutions which follows.

Of the 879 supervised institutions in New York State, twenty are conducted for delinquent children, while several receive only truants or those with improper guardianship. This does not take into consideration the various orphanages, many of which accept delinquent or neglected children under special conditions, or of the mentally defective delinquents in the several State Schools for Feeble-minded. Of the group of twenty just mentioned, three are controlled exclusively by the State, seven are maintained by the Roman Catholic Church, four are non-sectarian, two are Jewish, one Protestant, two Episcopalian, and one is municipal in management and is under the local Board of Education. Its scope is becoming increasingly delimited to the care of the truant child. Approximately six thousand children are cared for in this manner, less than a third of which are in State institutions. It should be recalled in this connection that with a single exception all the private institutions carrying on this most important program receive a considerable share of their funds through public contributions. Analyses of their various capacities show that the State institutions can care for 2,124 children or 26 per cent, the Catholic organizations 4,042 or 60 per cent, non-sectarian 832 or 11 per cent, Jewish 478 or 6 per cent, Episcopalian Churches 295 or 5 per cent, and Protestant 57 or 1 per cent. Thus it will be seen the study resolves itself into the considera-

gin to exhaust the list of all skin conditions, in which the X-ray could be used to the greatest advantage, but to enumerate them all would be entirely out of the scope of this paper

Next in importance after the X-ray as a physical therapeutic agent, I consider the high frequency current, especially as utilized in the modern diathermy or endothermy apparatus. Two modalities are in use, either the monopolar or desiccation method, or the bipolar or electrocoagulation, in both these methods the great heat which causes the destruction is created after the electrode has been brought in contact with the tissue. Desiccation is the most ideal method for the destruction of all skin blemishes of a small or moderate size, such as moles, warts, pedunculated nevi or any other benign skin tumor. As a rule, one or two applications are sufficient, the procedure is very rapid and not painful enough to even require a local anæsthetic. The resulting scar is cosmetically as good or even better than produced in any other way.

Electrocoagulation is preferable for the destruction of larger tumors, as its effect is more intensive and penetrating, here a local or even a general anæsthetic is recommended. To my mind, this is the best method for the destruction of a basal cell epithelioma, which I usually follow up with an intensive X-ray application, more as an extra precaution than in the belief that it is really necessary. Since using diathermy, I have discarded the application of electrocautery or electrolysis, although both these methods give very good results, but they are not as flexible and quick in their action as the former. Of late, I have been experimenting with diathermy in the treatment of hypertrichosis. This most disfiguring condition seems to be the greatest tragedy in a woman's existence, and a safe and reliable method for its cure will be a great boon. Beauty parlors and unscrupulous doctors have pried on the gullibility of these unfortunate sufferers, because the legitimate profession has rather been lax in helping them. Of late, the X-ray has been exploited for this purpose, but should be

strongly condemned, as in most instances the sequelæ are disastrous and by far worse than the original trouble. Electrolysis is safe, but very slow, painful, and followed by a large percentage of recurrences. When employing the endothermy, I use the same technique as with electrolysis, but have found that it takes much less time to destroy the hair, that the percentage of recurrences is much smaller, and that it is less painful.

Carbon dioxide snow, introduced in dermatological practise about twenty years ago, has to my mind undeservedly been relegated to a place of minor importance. I still use it quite often for the removal of various types of nevi, which are broadly attached to the skin, especially in vascular nevi of a hypertrophic type. Carbon dioxide is also an excellent remedy for the destruction of infiltrated patches in lupus erythematosus.

The quartz mercury lamp, either as the Alpine Sun Light or the Kromeyer Lamp, has become quite popular with dermatologists in the last decade or so. I feel that its usefulness in dermatology is exaggerated and that it has a broader field in general medicine, due to its tonic effect on the general system, which mainly accounts for its beneficial effect in tuberculous skin lesions. I have obtained good results from its use in stimulating indolent skin ulcers of various types. As to its usefulness in scalp conditions, for which the Alpine Lamp was especially highly recommended, my personal experience leads me rather to a conservative statement. In *Seborrhoea capitis*, it helps as an adjuvant to drug treatment, the same holds good in cases of alopecia prematura, in alopecia areata, good results may be accomplished, but in frank baldness it is absolutely worthless. As to its effectiveness in eczema, psoriasis, acne vulgaris and other dermatoses, where the X-ray is applicable, I can only give a negative opinion, as I prefer using the X-ray in these cases, because of its greater reliability.

PSYCHIATRIC PROBLEMS IN THE CARE AND MANAGEMENT OF DELINQUENT CHILDREN IN N Y STATE

By V C BRANHAM, M D, Psychiatrist,

(State Commission for Mental Defectives)

WITH the creation of the Children's Court as a special branch of the judiciary throughout New York State by Act of Legislature of 1922, a prominence was given to the study and treatment of juvenile delinquency which it had not hitherto enjoyed. Many of the justices called upon to sit in judgment upon these children met more baffling problems than

had come to their attention in other courts. Out of this situation has arisen the need for a greater knowledge of the various institutions other than prisons. Consequently, an analysis of the facilities which these several institutions have to offer the courts has become necessary for the proper final disposition of the wayward child with whom probationary care, placement and other extramural adjustments have been failures.

REPORTING THE ANNUAL MEETING

It has been the custom of the Publication Committee to publish the complete proceedings of the Annual Meeting of the Medical Society of the State of New York in the next issue of the Journal following the meeting, but since the Journal has been made a semi-monthly, the time is too short for the adequate preparation and editing of some thirty pages of minutes. However, this issue contains general accounts of the principal features of the four-day meeting, and a report of the year's progress.

These descriptions are more than statistics

and consecutive diaries. They are designed as word pictures of the outstanding events and actions, and are intended to convey to the members, throughout the State, the vivid impressions of the medical reporter.

To arrange a four-day meeting for over a thousand doctors is an immense task which was well performed by the President and his corps of officers and committees.

The meeting was practical and altruistic, harmonious and thoughtful, progressive and conservative, with a due regard for the ancient landmarks and ideals of the profession.

tion of the State institutions and the largest organizations of the Catholic, Jewish and non-sectarian faiths. These estimates are approximate, of course, but are considered to represent fairly accurately the situation. That the actual population is not up to the capacity of the institutions seems to be due to the increasing role probationary methods play in keeping the delinquent child in the community.

The State institutions have been colored largely by the personality of the director at the head of them. His appointment has been determined by factors diverse in nature and the methods employed by such appointees are necessarily wide. This has tended to result perhaps in the failure to see in the psychiatric department anything more than a mere testing apparatus. As a consequence, there is inability to utilize such resources in offering practical help to inmates with serious behavior problems or arrive at a better classification of the inmates with a view of securing in them a more adequate response to their environment. The outcome has frequently been a stressing of the repressive and disciplinary side of the management to an undue extent. Diversities in points of view are unavoidable and they even have their value, but the net result is often confusion as to the task to be accomplished. One of these three institutions has a psychiatrist, another depends upon the school director to act as psychologist, and the third has neither psychologist or a resident psychiatrist.

The situation in the private institutions, of course, is somewhat different. These institutions fall broadly into the religious and non-religious organizations. The ideal of the former group, naturally, is to provide a home for wayward children in which the spiritual element is stressed. This is important, but not conclusive. Very few of these have a psychologist or psychiatrist, but many of them are located in metropolitan districts, which afford clinical facilities in this respect. The main difficulty with this arrangement is that the director of such an institution does not possess the viewpoint which will cause him to make full use of these facilities. Even testing of intelligence is not resorted to except as a means for the convenient disposition of a low grade defective. There are one or two notable exceptions to this, especially in the Jewish institutions.

Some of the private institutions appear to have secured a better grasp of the possibilities of vocational, industrial and recreational activities. The poor use of psychologists and psychiatrists is also more widespread. In many instances this service, however, is secured

through a consulting staff, and the impetus for developing such work has to arise for the most part outside the institution. But here again there are exceptions, and at least one institution has brought its departments up to modern requirements.

The foregoing remarks are not made in a spirit of criticism, of course, for it is recognized that the belief in the mental hygiene approach to behavior problems is a comparatively new one. This movement meets very much the same obstacles that were encountered by the crusades against T. B. and cancer. The institutions as a whole have been no more backward in accepting modern methods than has the community at large. The discussion has been made constructively with the viewpoint that psychiatric service in institutions caring for the maladapted child has much to offer. Such a service would secure better adaptation of the individual to his new institutional environment by correctly classifying him both as to his level of intelligence and mechanical aptitude or other abilities that best place him in the industrial unit of the organization. In this manner the vocational aspect of the treatment of delinquent children would assume ever-increasing importance. Such a service would study the child as an individual rather than en masse, with the desire to understand the fundamental causes back of his behavior. In its practical application it would secure better methods of discipline and care than a standard which metes out its punishment according to the degree of infraction of the rule. A study of the prison population brings out clearly the fact that a large proportion of inmates are subject to emotional instability and mild trends. Few of these are definitely insane in the current acceptance of the term. Likewise, the delinquent child shows the same maladaptations, and his conduct and his treatment should be governed accordingly. The prognosis of the child is more definitely predicated by this method, which has its practical application in the matter of consideration of parole. Finally, the child no longer becomes a cog in a machine. He is a human being with divergent physical, emotional, instinctive, and spiritual aspects which give promise of readjustment under a regime that stresses the individual rather than the mass. All institutions, of course, cannot be maintained by the State, but it is possible to secure for those concerned in the treatment of the delinquent child suitable State supervision and the physical, social and psychiatric care that is to be found as a regular procedure in the State hospitals and institutions for the care of the epileptic and feeble-minded.

2 The encouragement of writing for the local press by gifted physicians, who write over their own signatures as representatives of the medical societies

3 Participation in the activities of boards of health, child-welfare societies, and school boards, and other civic organizations

4 The promotion of the practice of periodic examinations of apparently healthy persons

While these four activities have had a gradual growth, they have been formally recognized only during the last year or two

An activity of first-class importance instituted during the past year is that of Graduate Edu-

cation, in which lecture courses and demonstrations are brought to doctors in their own counties. These courses have shown that while physicians are willing to assume the civic responsibilities that belong to the medical profession, they also wish to give the people the advantage of the newer scientific discoveries. These courses have also been great factors in inspiring physicians with a pride in their profession and with a sense of their civic responsibilities in medical affairs. Activity in one line of endeavor stimulates interest in other lines. Graduate education is the key which has opened up allied fields of work for county medical societies and individual doctors

HEALTH DEPARTMENT OF NEW YORK CITY

The Commissioner of Health of the City of New York, like a high ranking Medical Officer of the Army, does little medical or surgical work, but his time is occupied with administrative duties. He is the official head of public activities which have a bearing on health and for which no other agency is provided. It has been the fashion of public health writers to criticize the assumption of control over nuisances by a health department when some other branch of government could properly assume it. But some of these conditions come under the direct control of the Commissioner of Health of New York City because their health relations supply the best basis for action.

The most evident nuisance with which the Department of Health has dealt recently is that of smoke. The exact extent to which smoke is detrimental to health may not be susceptible to demonstration, but sentiment of the people and of the medical profession supports the Commissioner of Health in his efforts to eliminate the nuisance. Physicians see the discomforting effect of smoke on sick people, and they believe that the soot and tar and sulphuric acid in the murky air are important factors in producing respiratory diseases. The doctors of New York City are deeply interested in the relation of smoke to their practice of medicine.

Transportation problems would not ordinarily seem to come under the jurisdiction of the Department of Health, but the physical discomfort and danger of infection on crowded cars make human travel a first-class health problem. The solution seems to be to rearrange the hours of

opening and closing of offices and theatres. The administrative problem before the Commissioner of Health is to arrange a time schedule so that the half-hour of maximum travel, morning and night, shall be spread over an hour and a half to the great relief of the public as well as of the transportation companies. Physicians consider that transportation problems of the city have a great effect on their practice of medicine.

A third problem before the Department of Health is that of the purity of milk supplies and of fraud in connection with their adulteration. The detection of graft in the distribution of milk would seem to belong to the Departments of Police and Law, but their actions are based on public health to a greater extent than on fraud and crime. The Commissioner of Health therefore must perform the duties of a detective and a lawyer as well as those of a physician and chemist and milk inspector. It is also self-evident that the physicians are deeply interested in the purity of milk supplies.

Smoke transportation and milk frauds are largely emergency health problems for which adequate machinery is not provided. It is gratifying that the presidents of the five county medical societies of Greater New York have accepted the invitation of Commissioner Louis I. Harris to advise them regarding these and other public health problems. It is reassuring to the people of New York City that the daily papers have given publicity to a recent conference of the presidents of the Medical Societies with the Commissioner

LOOKING BACKWARD—THE JOURNAL TWENTY YEARS AGO

One who reads the JOURNAL and the records of the Medical Society of the State of New York, made twenty years ago, will find that the actions of the present day leaders were anticipated long ago and that the principles governing medical societies and public health were then formulated in their modern form.

This JOURNAL for March, 1906, contains a two-column letter from Dr. E. Eliot Harris, the present live and active Speaker of the House of Delegates. Dr. Harris argues against the recognition of osteopaths. If the word chiropractors was substituted, the letter would be entirely modern. We read

IDEALS AND ACTUALITIES OF THE ANNUAL MEETING

The Annual Meeting of the Medical Society of the State of New York, like all other meetings of the kind, passes through three stages of existence. The first is the meeting that is planned, the second is the meeting that actually takes place, and the third is that which the doctors remember. These three phases may be called ideals, achievements, and impressions.

The ideals of the 1926 meeting were born at the close of that of 1925 in the minds of seers and prophets who compose the staffs of officers and committees of the State Society. Gradually the visions of these inspired men assumed form and substance as they came in contact with the members throughout the State, until at last the program was evolved in every detail.

The amount of time and thought that is required to make a program is surprising to the uninitiated. Consider these figures:

Number of participants in the Scientific program	135
Number of lecturers and demonstrators in the Syphilis Exhibit	50
Officers and Committeemen	25
Delegates	150

Total participants on the formal program 360

It takes imagination and vision to coordinate the activities of over three hundred participants in a program and to visualize each section and

department at work, not only as a unit but as a component part of a complete meeting.

The acid test of the practicality of the ideals of the program makers was the four day meeting, the outlines of which are described on page 335 of this Journal. A Methodist Bishop once said that a good prayer meeting was one in which *you* took part. It is no wonder that the meeting of the State Medical Society was a "good" one, when one third of those registered took an active part in the formal programs.

The meeting now exists as vivid impressions in the memories of those who were fortunate enough to attend it, and as pages of history and records and papers in this and other Medical Journals. These impressions are as varied as those of the five blind men who first examined an elephant by means of the sense of touch. Some remember the sociability and the conversations with their fellow-workers in the corridors and dining rooms, some recall the discussions in the scientific sessions, some carry away vivid impressions of medical politics, some will study the subject of syphilis with renewed interest because of the impression of the exhibit, and some will go home renewed in youth and vigor because of the stimulation of the high lights of Broadway.

The ideals of the Medical leaders are well realized in the actualities of the meeting and in the favorable impressions carried away by those in attendance.

PROGRESS OF THE YEAR

The officers and committee of the Medical Society of the State of New York have given detailed accounts of their stewardships for their year of responsibility. It is well to take a birds-eye view of the collective attitude of the members of the Society toward the activities of the State organization.

The annual dues of the Society were doubled at the Annual Meeting of 1924, and were made ten dollars on the assurance of the leaders that more funds were needed for the activities that were demanded by medical progress. The attitude of the members was that the Society should enlarge its field of work, and that they were willing to bear the increased expense, provided the results justified the cost.

The four major activities which have absorbed the funds of the Society for many years have been continued and enlarged during the past year. These four activities are 1, the routine conduct of the central office, 2, the publication of the Journal, 3, the preparation of the Annual Directory, and, 4, provision for medical defense. These activities are concerned chiefly with doctors as individuals, and they differ from the corresponding activities of twenty years ago chiefly in their

greater extent. Provisions for the office of President Elect and for a permanent Board of Trustees will insure a continuity of policies and plans which has been lacking when the whole administration changed every year.

The great development of the activities of the State Medical Society in recent years has long been along civic lines. Physicians have always aspired to assume the leadership in all civic matters in which health is involved, but if an individual presumed to speak for the medical profession, his colleagues and the public questioned his authority and his motive. The past year has seen the quiet development of medical sentiment that the medical societies of the several counties and of the State should speak through their representatives, and should give qualified physicians the authority to speak and write and act in the name of their fellows.

The results of the assumption of civic duties by medical societies are far-reaching, and four may be emphasized.

1. A spirit of cooperation with the lay health organizations as outlined by Mr. Homer Folks in his address at the Annual Banquet (see page 339).

MEDICAL PROGRESS

The Causes and Control of Cancer—In an article in the *Medical Journal and Record* of March 17, 1926 (cxxxii, 6), James Young says he has for a number of years been urging that cancer is a parasitic disease and that in the transformation of a normal into a cancerous cell there are concerned (a) the factor that prepares the cell for the action of the parasite, and (b) the parasite, and only when these two factors are conjoined is cancer possible. After discussing the characteristics of the parasite, he emphasizes the importance of focusing attention not only on the local causes but on the possible and even probable operation of some generalized agencies which, in an increasing degree, are conspiring to make the peoples of civilized communities more liable than their predecessors to suffer from the damaging effects of tissue irritants. All the evidence indicates clearly that the absence of alimentary cancer in the primitive races must be due to alimentary habits that do not excite local irritation of the mucous lining of the digestive tract and that, *per contra*, the large incidence of alimentary cancer in civilized communities must be due to alimentary conditions that provoke irritation. In the ultimate the most important of all classes of cancer can be traced to considerations of diet. It cannot be said that such and such a food is especially responsible for cancer, but it can be said that any food irritant whatsoever is suspect, and it can be taught that by the practice of the well-recognized principles of a simple dietary much can be done to avoid the most frequent form of human cancer. To have the greatest possible effect the observance of enlightened hygienic rules must commence in infancy, for, as Sir Arbuthnot Lane and others have shown, bad alimentary habits started in early years may lead to permanent mechanical damage of the bowel, associated with bands and kinks and with chronic intestinal stasis and irritation, that in later years not only establish a condition predisposing to cancer but determine the sites of the neoplasms.

Parasitic Origin of Malignant Disease—Blumenthal, of the Berlin University Cancer Institute, in an article in the *Deutscher medizinische Wochenschrift*, March 5, 1926, reviews the work of himself and colleagues in this direction and also that of Gye and Barnard. The author admits that the present day pathologist is hostile to any parasitic theory of malignancy, so that certain objections must first be met, one of which relates to the nature of metastases. If cancer were a parasitic disease the metastases would have to consist

largely of proliferated microorganisms, as in the case of all true infectious metastases. Instead, they consist of proliferated cancer cells and of nothing else. In rare cases in which some microorganism can be shown to have caused the primary growth, this formation is not found in the metastasis. In replying to this objection Blumenthal assumes that there is a cancerogenic virus which has been responsible for the initial growth and that this virus may also cause the metastases, basing the conclusion largely on the statement of Carrel that *in vitro* the virus of fowl sarcoma changes the blood macrophages into malignant cells. This find also appears to dispose of the belief that fowl sarcoma is not a true tumor but only an infectious granuloma. Again, E. Smith, the discoverer of the bacillary cause of plant cancer, has gone over the work of Gye and certifies that the virus cultivated by the latter is of the same nature as that of fowl sarcoma. What now is the relationship of Blumenthal's living virus to the other forms mentioned? It is not necessary that it shall belong to the same group. Carrel has shown that tar cancer is not due to a living virus but a physicochemical one. Here we have two separate etiological factors which may have to cooperate before a cancer can originate. The living virus may require the other to activate it. The author thinks it best to limit his claim to this, that he can cultivate a bacillus from human cancer, cultures of which are able to cause animal cancer.

Radio-Diathermy in the Treatment of Inoperable Malignant Disease of the Upper Air and Food Passages.—Sir William Milligan states that when, owing to the situation, size, and extent of a malignant growth, surgical procedures are contraindicated, great relief, and in a certain proportion of cases apparent cure, may be effected by the employment of surgical diathermy, or by the use of radium or by a combination of these two methods—in other words, by radio-diathermy (*British Medical Journal*, February 27, 1926, 1, 3400). Diathermy, or endothermy, is contraindicated in cases of large adherent growths, growths in the intestinal tract, and when there is marked cachexia. Small and accessible growths are destroyed by this method, large growth only as the result of repeated application. In many cases it is possible, by means of block dissection, to remove all infected glands, and by subsequent irradiation to secure the sealing up of lymphatic tributaries in the dangerous zone with the result that what was surgically an inoperable growth becomes an operable possibility. The most brilliant and lasting results are to be

"Sir The attention of the medical profession in this State is called to a bill introduced in the Legislature by Senator Hinman, entitled "An Act Regulating the Practice of Osteopathy in the State of New York"

"Osteopathy, as defined in the bill, means "That science or system of healing which treats diseases of the human body by Manual Therapeutics for the stimulation of the remedial forces within the body itself, for the correction of misplaced tissue, and the removal of obstructions or interferences with the fluids of the body, all without the internal administration of drugs or medicines"

"Osteopathy means manual or hand therapeutics, and is a single agent used in the treatment of disease, as such, it has no greater claim to be separated from the general practice of medicine than electricity, or electropathy, bathing or hydrotherapy, massage or kinesiopathy, X-ray or radiopathy, and mental science or psychopathy, and is not entitled to a special examining board. The eye, ear, nose, throat, electro-therapeutic, psychopathic and other specialists do not ask exemption from the examination in the general science of medicine demanded by the Regents of the University of the State of New York of all candidates who apply for a license to practice medicine, or any branch of medicine, and they do not ask for an examining board in their specialty. If the so-called Osteopaths desire to establish a special branch of medicine, then they, too, should possess at least that average of the knowledge of preventive medicine, which is needed to properly control the spread of contagious and infectious diseases, and is included in the general science of medicine demanded by the present law which governs the granting of a license to practice medicine in this State, and they should not try to escape, under the said Section 6, the preliminary and final examinations for a license to treat the diseases of the human body by securing the enactment of the so-called Osteopathic Bill, which permits certain so-called practitioners in this State to receive a license to treat the diseases of the human body, without passing an examination,

and without presenting evidence of the possession of any scientific knowledge of the etiology, diagnosis, and properly quarantining of contagious and infectious diseases, and the methods of securing immunity from such diseases, which produce a terrible mortality throughout the world."

"The public has so long suffered from poorly educated physicians that every State in the Union has enacted laws, raising the educational qualifications of the candidates to be examined for a license to practice medicine."

"The medical laws of the State of New York were enacted to protect the people of the State from charlatans, quacks and pretenders of all sorts. The four years spent in the study of medicine prepares the mind and molds the character along the lines of truth and science and away from commercialism in medicine. A reaction from commercialism in medicine, and the tendency of modern times to raise rather than lower the educational standard of professional men were factors in causing the Legislature to enact the laws which prevent any person, not presenting the intellectual and moral qualifications required by the law, from practicing medicine "or treating disease of the human body" in this State. The public is protected by discouraging commercialism in medicine and is benefited by fostering the science of medicine, and not the least of the duties of physicians is the guarding of individual and public health along the lines of sanitation and preventive medicine"

"And it would be more reasonable for the Legislature to separate the special branches of criminal, corporation and real estate law from the general practice of law and establish for each of them a special examining board, so as to make it easier for the candidates for admission to the Bar who desired to practice as specialists, than it would be for the Legislature to select one special therapeutic agent used in the treatment of disease and separate it from the general practice of medicine as a panacea for all diseases at the request of those enthusiasts who are now asking for a special osteopathic examining board"

to the manner of action of the so-called alkaline diuretics which are given *ad libitum* in a host of conditions. The fact is lost sight of that they do not act by a true stimulation of the kidneys, but rather induce an increase in urine output because the system cannot tolerate an excess of these salts, since it must maintain a normal tonicity of its fluids at 0.9 per cent. To give them without plenty of water to wash them out is evil, for if the potash cannot escape, the body retains water to keep the salt diluted to its normal tonicity, the heart is depressed, and the patient becomes dropsical. Again the question arises as to whether direct diuretics should be continuously given or whether the kidneys should have periods of rest. That Nature means them to rest is manifest. In regard to other diuretics, such as digitalis, there is too little appreciation of the fact that any diuretic effect depends upon three factors, namely, whether the body is provided with enough water to be able to part with it, whether the oliguria depends upon the presence of a feeble heart which if improved will increase renal pressure, and whether the ability of the kidneys to eliminate water is the particular renal function impaired by disease. If this function is impaired the ordering of large amounts of water cannot be other than hurtful. As to the use of diuretics in the presence of acute nephritis, we are even more frequently in error. If one keeps in mind the pathology of the acutely inflamed kidney, one will not expect such a kidney to function either with or without the spur of diuretics. An estimation of the chlorides in the urine may be taken as a fair gauge of the ability of the kidney to eliminate salts. It is still easier to use the Mosenthal plan of recording specific gravity every two hours in the daytime, being careful to note the intake, which should be standardized and measured as well as the output. It must also be borne in mind in the consideration of diuretics that secreting epithelium, which is still capable of acting, bears in addition to its already heavy burden of urinary solids in fever the further burden of drugs.

Intradermal Salt Solution Test in Cardiac Disease in Children.—In 1923, W. B. McClure and C. A. Aldrich reported that when 0.2 c.c. of an 0.8 per cent aqueous solution of sodium chloride was injected intradermally in children, the resulting elevation disappeared or became impalpable much sooner in edematous patients than in certain control patients without edema. In a later paper they pointed out that the decreased disappearance time found in remotely separated regions of the body in the same subject could be explained on the assumption that a general intoxication so altered the tissues as to increase their avidity for water. Harry C. Olmstead (*Archives of Internal Medicine*, February 15, 1926, vol. 2) describes his experience with

this test in 47 children with rheumatic heart disease, or allied conditions. It was found that the disappearance time of intradermally injected salt solution was normal (above fifty minutes) in well compensated nontoxic cardiac disease, acute rheumatic fever, and chorea. In cardiac decompensation with edema, shortening of the disappearance time was limited to edematous and pre-edematous regions and was noted earliest in the dependent parts of the body. Decrease of disappearance time did not precede other clinical signs of impending decompensation with sufficient constancy to make the test of much value in predicting a break in decompensation. In certain severe cases of cardiac disease without decompensation there was a marked and nearly equal decrease in the disappearance time in arm and leg. The intradermal salt solution test was of value in this generalized or toxic group as indicating an unfavorable prognosis. The disappearance time picture characteristic of the toxic group was altered in the direction of that characteristic of the decompensation group, if cardiac decompensation developed. In two patients tested after death, the disappearance time in the edematous parts was practically as short as during life. This demonstrates that under these conditions circulation of the blood is not necessary in the phenomenon of disappearance of intradermally injected salt solution.

Vagus Heart.—Frey takes up a recent theory which may be destined to modify greatly or to do away altogether with the conception of vagotonia, which is in many respects unsatisfactory. The term "vagus heart" means for many internists the heart of vagotonia, yet in some of the most exquisite vagotonic diseases the heart shows little or no participation. On the other hand electrical stimulation of the vagus causes a wealth of symptoms which involve most of the organism and its functions and yet bear little resemblance to the clinical vagotonia of authors. For example, it causes calcium retention or at least a calcium increase in all of the tissues, while the state of the heart resembles that of muscarine and quinine poisoning. If the entire vegetative nervous system is stimulated the general result makes it very difficult to uphold the old doctrine of vago- and sympathicotonia. The author, basing his views on an analysis of the large amount of recent research in all countries, advances a different hypothesis. There is in certain individuals a special vagus sensitiveness, which belongs to what has been called the parasympathetic constitution. There is no primary participation of the vagus which is involved only secondarily. The causal elements are largely peripheral. This vagus sensitiveness should bear the name of vagus heart. The author seeks to trace the presence of this element in bradycardia, extrasystoles, paroxysmal tachycardia,

obtained in electrocoagulation of malignant growths and areas of ulceration in the upper pharyngeal cavity—the palate, tonsils, base of the tongue, and floor of the mouth. The infected glands are first removed after ligation of the external carotid artery and this is followed ten days to a fortnight later by ligation of the other carotid artery and coagulation of the primary seat of the disease. Irradiation may be effected either by burying radium needles along the route of the lymphatic stream leading from the focus of the disease, by means of applicators applied around the angle of the jaw, or by a combination of both methods. In malignant growths of the esophagus, an electrode recently designed by Wright of Bristol renders the application of diathermy easier and safer than any other, as it coagulates upward, and therefore under the observation of the operator. If it is desired to radiate with radium, an endless thread to which one, two, or three screened tubes containing radium element are attached, is swallowed and the tubes are pulled into position in vertical series. The preliminary coagulation and consequent opening up of the stricture will be found to permit of this being done comparatively easily. In all cases the performance of a preliminary gastrostomy is advisable. Diathermic coagulation, with or without the subsequent employment of radium, affords a chance, although a very slight one, of eradicating malignant disease of the esophagus. Diathermy is followed by little shock, is a practically bloodless operation, prevents dissemination of cancer cells, affords relief from obstruction and dyspnea, arrests the tendency to spontaneous hemorrhage, gives soft and pliable scar tissue, and is less frequently followed by bronchopneumonia than are cutting operations. It has the disadvantage that it destroys a certain area of healthy tissue around the growth, it may cause softening and ulceration of blood vessels, with resulting secondary hemorrhage, and when the skin is involved keloid cicatrices may develop.

Fifteen Cases of Operable Carcinoma of the Breast Treated by Radium and X-Rays—While not maintaining that radiation should be preferred to operation in operable cases of breast cancer, J. H. Douglas Webster, J. P. Thierens, and F. G. Nicholas, none the less believe that this modality which has sometimes led to the complete disappearance of inoperable growths, should give good results in operable cases (*Lancet*, February 27, 1926, ccx, 5348). They report fifteen operable cases—8 treated by x-rays, 2 by the combined use of x-rays and radium, and 5 by radium—in 11 of which the patients are well, with little or no sign of disease. There were two deaths, one due to an intercurrent disease, and one to the malignant disease over two years after treatment had been discontinued, in one case there was abdominal metastasis. Com-

paring the radium with the deep x-ray cases, the writers found no notable difference so far as the results were concerned. All the radium cases did well locally during the time they were under observation. In each case there were supplementary medium-voltage x-ray applications to the epigastrium, lateral chest wall and axilla, supraclavicular triangles, opposite axilla and breast. Every patient in the series either refused operation, or else age, chronic bronchitis, heart disease, or glycosuria made operation inadvisable. These results suggest that cancer patients should be more freely offered the alternative of radiation treatment than they are at present, at least they should not be told that there is absolutely no alternative to operation.

Erythema Arthriticum Epidemicum—Edwin H. Place (*Boston Medical and Surgical Journal*, February 18, 1926, ccxiv, 7) describes an epidemic of an apparently new type of disease which occurred in Haverhill, Mass., a city of about 55,000 population, in January, 1926. The clinical picture in this disease is dominated by (1) the acute onset with toxic symptoms, as chill, vomiting, malaise, and headache, (2) the eruption, involving especially the extremities, of a blotchy somewhat morbilliform character with a tendency to petechiæ, and (3) acute multiple arthritis of varying but often severe degree. The disease appeared to be readily distinguishable from the ordinary epidemic diseases. An organism was isolated from the blood in ten out of twelve blood cultures. One negative blood culture was from a patient on the tenth day of the disease, the other was badly contaminated with staphylococcus. The organism was also cultivated from two joint fluids, one being from a patient whose blood had yielded the organism at two different times. This organism is a Gram negative, rod-shaped microorganism, growing in fluid media as long filamentous threads which often show oval or spherical enlargements, occurring at any point on the filament, in these fluid media, the organism tends to grow in masses of interwoven threads. The best media found thus far are ascitic fluid broth and blood broth. The disease seems to come in the group of undulant fevers and most closely simulates Malta fever. The association with the milk supply, the arthritis, eruption, toxic symptoms and the irregular fever are similar. The milk supply of those affected was either directly from one dairy or indirectly through four stores receiving the same supply from the dairy, except in two cases. The epidemic was confined to a small area along the river. The patients were chiefly Lithuanians.

Certain Therapeutic Considerations in Connection with Renal Disease—Hobart Amory Hare (*Therapeutic Gazette*, February 15, 1926) calls attention to a misconception that exists as

LEGAL

By LLOYD PAUL STRYKER, Esq
Counsel, Medical Society of the State of New York

INDIVIDUALISM—ITS MERITS AND ITS DANGERS

English history is the record of the struggles for individual liberty. The story of the Great Charter wrested by the Barons from King John at Runnymede in 1215, the contests with the Stuarts, the wars of Oliver Cromwell, and his parliamentary army, furnished an inspiration and a precedent to the contemporaries of George Washington who offered their lives in the cause of liberty.

The opportunity for the individual to lead his own life, free from arbitrary trammels, to think, to act and to engage in the pursuit of happiness in his own way, is the ideal, the excuse and the underlying basis of our democracy. Individualism—the right of each individual to think his own thoughts and to be the captain of his own destiny, furnishes the key to an understanding of the genius of our American principles and explains the development within the short space of a hundred and fifty years, of the mightiest nation known to human annals.

Liberty, however, does not mean the right of each man to live in disregard of the rights of his fellowmen. Liberty is reciprocal, it involves duty as well as right. Liberty, even under a free constitution, presupposes the duty of the citizen to exercise so much liberty only as is consistent with the liberty of others. Thus our government, which guarantees our liberty in a sense, curtails it. Liberty is not license.

As civilization grows more complex, the necessity rises for each individual to surrender a part of the rights which he might enjoy in a state of nature increases. This is the price which he must pay for the protection which the government affords him. Thus, while the citizen has the right to except his government to protect him from invasion of a foreign foe, he must, in order to secure this right, be ready to need be to become a soldier and to lay down his life for the government which protects him. For the privilege of having his disputes adjusted by a court, for having his streets policed, his house protected from fire, his food inspected through proper sanitary measures, he must pay taxes. Within our own time we have watched the obligations of the citizen multiply and increase. Every year at the expense oftentimes of personal convenience each of us is required to prepare a detailed and voluminous statement of our income, both for

the national government and for the state and to take from our income, for the support of these governments, a portion of that which we have earned. For the privilege of good roads and the right to drive our automobiles upon them each year we are required to apply for and obtain an automobile license, and to pay the fee which the government exacts. By thinking men these things are now cheerfully done because they realize their purpose and their necessity.

There is no field of endeavor in which individualism is more necessary than in the medical profession. The doctor is an individualist. It is both well and necessary that this is so. Granted the proper professional training and knowledge, the physician should be free to exercise his best judgment and in his valiant struggle against disease and death to bring to bear unhampered all his skill, personal judgment, knowledge and experience which he can summon to the mighty combat in which daily he engages. No friend of the medical profession could bemoan this or wish to change it. And yet there are times when the individual physician, oppressed by the manifold duties and responsibilities which flow from the high calling which he follows, is prone to forget that the attainment of the great ends to which he has dedicated his life—the safeguarding and protection of the public health—can best be served by combined action rather than by working alone. It was the recognition of the necessity for cooperation which prompted the organization of the Medical Society of the State of New York in 1806. "The purposes of the Society," so reads the first article of its Constitution, "shall be to federate and bring into one compact organization the medical profession of the State of New York, to extend medical knowledge and advance medical science, to elevate the standard of medical education, to secure the enactment and enforcement of just medical laws, to promote friendly intercourse among physicians, to guard and foster the material interests of its members, and to protect them against imposition and to enlighten and direct public opinion in regard to the great problems of medicine."

"To secure the enactment and enforcement of just medical laws." "To enlighten and direct public opinion in regard to the great problems of medicine." Where is there a more

auricular flutter, conduction disturbance, acute cardiac failure, acute dilatation, etc. Especially characteristic of this conception of vagus heart are the disturbances of rhythm. Ordinary vagotonia may coexist but is not necessarily present. —*Klinische Wochenschrift*, February 12, 1926

The Tragedies of Tooth Extraction and of the Treatment of Root Abscesses—George Blumer (*Boston Medical and Surgical Journal*, February 11, 1926, cxciv, 6) calls attention to some of the types of infection which may follow the extraction or treatment of infected teeth. He cites two cases as examples of general sepsis following in the one case the extraction of an infected tooth and in the other the drainage of a root abscess. In two other cases the simultaneous extraction of a large number of teeth was followed by a nonfebrile process, evidently of an infectious nature. In one of these cases there were visual disturbances due to old and fresh retinal hemorrhages, thickened peripheral vessels with hypertension, slight heart hypertrophy and albuminuria. Extraction of infected teeth was followed directly by vomiting, weakness, jaundice, increasing diminution of the liver dulness, restlessness, muscular twitching, stupor, and death in a convulsion. In the other case, a few days after the removal of the upper set of teeth for pyorrhea, pain in the hip joints, anorexia, nausea, vomiting, dizziness, and slight dyspnea on exertion appeared. There was slight elevation of blood pressure, with the persistence of gastroenteric symptoms there was high nonprotein nitrogen and very low phthalein excretion. A diminution of urinary secretion followed with increasing lethargy and death. Autopsy revealed chronic infectious nephritis, extensive degenerative lesions in the liver and heart muscle, and latent carcinoma of the prostate. The different types of fatal lesion which may result from tooth infection may be grouped as follows: (1) Direct extension of the local inflammatory process with spreading inflammation, which may even invade the mediastinum, and death from toxemia, (2) metastasis to neighborhood tissues, such as occurs in cases of meningitis or thrombosis of the cerebral sinuses following tooth extraction, (3) general septicemia or septicopyemia, which may terminate in (a) acute septicemia with or without endocarditis, (b) chronic septicemia with degenerative processes in the internal organs, or (c) prolonged septicopyemia with the formation of abscesses. In patients whose general resistance is lowered by chronic disease, infected teeth should be removed under the most favorable circumstances and with the most careful technique.

The Treatment of Salpingitis—The differentiation between acute salpingitis and acute appendicitis often raises a problem very baffling to the surgeon. Thomas G. Stevens (*The Lancet*, January 23, 1926, ccx, 5343) states that on the whole there is more to be discovered by a pelvic examination in acute salpingitis than in appendicitis. One peculiar sign of great importance is the acute pain which is evoked in tubal inflammations by attempts to move the uterus. In doubtful cases an examination under an anesthetic should never be omitted, bilateral thickening of the tubes and of the structures around them, definitely excludes appendicitis. In salpingitis there is never the same necessity for immediate operation as there is in appendicitis. If an operation is done in the acute stage of a first attack the temptation to remove both tubes is very great. It has been shown, however, that it is not necessary to remove these pus dripping tubes. If they are freely split up and the pelvis drained, preferably with a large tube, through a small stab wound outside the rectus muscle, the results are very good. This is the treatment recommended if the abdomen is opened in a case in which it is doubtful whether the appendix or the tubes are at fault. Since it is not yet known whether tubes treated in this way will ever function normally, or whether cases thus treated can be regarded as cured, it is advisable that a first attack of acute gonorrheal salpingitis and peritonitis should be treated on expectant lines, and operation performed only if complete resolution does not occur. The expectant treatment to be adopted is chiefly concerned with the relief of pain and the promotion of the absorption of inflammatory exudates. Pain is best relieved by hot applications to the abdomen and hot vaginal douches of physiological saline solution. When pain has subsided counterirritation may be employed in the form of ichthyol tampons or vaginal suppositories, also combined with hot douches, 10 per cent ichthyol in glycerin for the former, or 10 per cent ichthyol in cacao butter for the latter, being the usual prescription. Every other night is sufficient for the ichthyol, as it may prove irritating. If an acute puerperal salpingitis of streptococcal origin becomes localized, with free pus in Douglas's pouch, it is best to evacuate it through an incision made transversely across the posterior fornix. Where no definite pelvic abscess can be found, and the temperature, pulse, wasting, and leucocytosis indicate pus formation, an abdominal operation must be done, drainage should always be employed whether pus is found in the peritoneum or not.

American interests abroad and at home, so the individual members of your profession and of your county societies in 1806 joined together in forming your Medical Society to "federate and bring into one compact organization the medical profession of the State of New York."

Individualism is vital to your welfare, it

should be fostered and encouraged, but individualism which refuses to unite and to co-operate in order to bring about the greatest good for the greatest number may become a danger and a menace to the accomplishment of the great aims for which you have so nobly dedicated your lives, your strength and your high courage

LACERATION OF HAND AND INFECTION OF HAND AND FOREARM

In this action the plaintiff was a retail distributor of milk, and one morning while engaged in the discharge of his duties he cut the palm of his hand upon a broken milk bottle. He called upon the defendant for treatment, who found that the plaintiff had sustained a severe cut upon the surface of the hand, and after cleansing the same inserted several stitches. At the time the plaintiff called upon defendant he had a soiled rag wrapped around the lacerated hand. The physician advised him to take extra precautions in keeping the wound and its bandages clean, and to return to the defendant's office on the following morning. The plaintiff failed to return upon the following morning, but came back to the defendant on the second day thereafter, at which time the plaintiff told the physician that he had put some liniment on his hand. The bandage at that time was found to be very dirty. The physician removed the bandage and cleansed the wound, redressing the same with a clean sterile bandage, and advised the patient not to do any work which would require the use of the injured hand, and to return to him during the day if necessary, if not, on the following morning. This was the last time that the defendant physician was visited by the plaintiff.

Instead of returning to the defendant the plaintiff went to an adjoining city and there consulted a physician, complaining at that time of great pain in his hand, and the same being extensively swollen. The physician in the adjoining city, upon removing the bandage, found that the wound and hand were infected. He thereupon removed the stitches and widely opened the original wound, permitting considerable pus to escape. This physician ordered the plaintiff into a hospital, and kept him in bed with his hand elevated, and wet dressings constantly applied for a period of about four days. The infection, instead of sub-

siding, had extended over the entire hand and into the arm, requiring the making of numerous free incisions to permit drainage. The infection continued to spread for a period of several weeks, during which time it was necessary to make further incisions for drainage purposes. The virulency of the infection also required the removal of the tendon from the little finger, but no other essential parts of the infected member were removed. The arm and hand continued to drain for a period of weeks, and in the healing process a large amount of scar tissue had formed on both the hand and forearm, causing a large percentage of loss of function of the hand.

In his action instituted against the physician who had first attended him, he charged this physician with neglect in the treatment of the lacerated hand, and claimed that the spread of the infection and the subsequent loss of use of the little finger and impairment of function of the hand and arm were due to the defendant's improper treatment.

The case was tried for two days before a court and jury, the plaintiff testifying in his own behalf and likewise introducing the testimony of a physician in his effort to establish that the defendant's treatment was improper and produced the result complained of. Testimony was likewise introduced on behalf of the defendant. The plaintiff being unable to establish that the treatment given by the defendant caused or probably caused the blood poisoning, or that the natural and probable consequences of any omission upon the part of the defendant caused or contributed to the spread of the infection and the blood poisoning resulting in the injuries complained of, the trial court, upon the defendant's motion at the close of all the evidence, dismissed the complaint, terminating the action in defendant's favor.

exalted aim? These purposes for which your great Society was formed should be ever before you as a pillar of fire to light the way to progress. No individual doctor or single group of doctors in any locality, however gifted, however unselfish or however lofty in its purpose, is strong enough to achieve these aims unaided. It was in recognition of this that your Society was organized "to federate and bring into one compact organization the medical profession of the State of New York."

Composed as it is of more than ten thousand members, it could not be possible for your Society or for any other society at all times to achieve absolute unanimity of opinion. Perhaps the difficulty of achieving unanimity increases in proportion to the enlightenment and to the self reliance of the group seeking to attain it. But in order to avoid frustration of its purpose, to prevent a complete dissipation of its energies and the defeat of its aims, it is necessary in this Society, as it is necessary in government, that the majority should rule. The privilege of every citizen to express his opinion at the ballot box does not carry with it the corollary right to disobey the laws which the Legislature by its majority has enacted. The essential of liberty is that the majority should have the privilege of expressing its opinion, and the opportunity, if possible, to persuade others to adopt its views. But once the minority has had a full and free exercise of advocacy and has failed in its persuasions, the majority must have the untrammelled opportunity to act. Any other way lies anarchy. Anarchy in government has its prototype of ineffectuality in private bodies.

Your Society is organized upon the representative theory of government. It is too large and extends over too wide a domain to permit direct action of the members upon every question that arises. Your House of Delegates is your legislature and your executive functions are distributed among your officers, your council and your standing committees. To act at all your Society must act through representatives. Your representatives cannot act effectually for you unless they are supported in their action. Theirs is the responsibility of action, yours is the responsibility of supporting them in that action. The representative principle runs through every section of your Constitution and your By-laws.

To a degree perhaps unprecedented in our history, the medical profession is assailed now from without—not only the medical profession but the whole body of scientific knowledge which the physician brings to bear against diseases threatening his individual patient and the public health. The folly and knavery of the cults menaces the welfare of our people to a degree that has not yet been fully appre-

ciated or exposed. The enlightenment of the public and its education in the dangers that inevitably flow from the pernicious propaganda of the quacks is the most serious duty of the medical profession—a duty more imperative even than that which was recognized and accepted by the organizers of your Society a hundred and twenty years ago, when the expressed duty "to enlighten and direct public opinion in regard to the great problems of medicine" was solemnly placed in your character, as one of the great purposes of your organization.

Thomas Jefferson was the President of the United States when your Society was incorporated. The country had emerged from its belief in witch-craft and though the cultists of the present day were then as yet undreamed of the necessity "to secure the enactment and enforcement of just medical laws" was recognized and embodied in your charter as one of the high duties of the medical profession. If the "enactment and enforcement of just medical laws" was necessary then it is ten times more necessary now! Since that purpose was proclaimed the nineteenth century has been written into history and a quarter of the twentieth has intervened with all of the marvelous and unprecedented advance in science and the knowledge of the causes and proper treatment of disease.

The brigands of the public health of our day who for their own selfish and dastard purposes of private profit flaunt the teachings of a century and a quarter must be met, opposed and put down. This can effectively be done only through concerted action. The weapon for combating these enemies of the public health lies within your own hands—your Medical Society, organized as it is "to federate and bring into one compact organization the medical profession of the State of New York." To federate means to "unite by compact," compact means "firmly united," organization means "the act of arranging in a systematic way for use or action." One of the purposes of your Society, therefore, is to bring together "in a firmly united body for use or action the medical profession of the State of New York," and thereby to "extend medical knowledge and advance medical science." How is it possible to do this unless you operate as "one compact organization"—not sixty compact organizations, but one! The value and importance of individualism is recognized in our American theory of local self-government. The townships, counties and the states have their several functions, and they are important, but when the United States of America declares war, no township, county or state is permitted to dissent or to obstruct. Just as our Federal Constitution was adopted in order to secure "a more perfect union" for the protection of

NEWS NOTES

BULLETIN NO 6

March 24, 1926

The hectic season of the legislative period is at hand. The Assembly has offered the Senate a resolution that they adjourn on April 16th. The Senate is holding the resolution, however, for a few days while it determines whether or not to amend it extending the period.

Our Trustee bill has been signed by the Governor.

The Loomis bill is with the Committee on Revision and it is hoped will appear on the desks in the Assembly Thursday or Friday, but will not come up for debate until Tuesday or Wednesday of next week. In the Senate it remains in the Public Health Committee. A group of advertising physicians, known as the American Association of Independent Physicians, whom we believe is headed by Leonard Landis, the man who conducts and advertises the House of Health in New York City—has been granted by Senator Karle an opportunity to oppose the Medical Practice Act at a hearing this Wednesday afternoon. We have invited a number of people who are thoroughly familiar with the manner in which the House of Health is conducted and the unethical practice the physicians engage in, to attend the hearing and give the Committee the benefit of their investigations.

LET EVERY COUNTY CHAIRMAN IMMEDIATELY WRITE TO HIS LEGISLATORS AND ADDRESS THEM AT THE CAPITOL ALBANY, URGING ON BEHALF OF HIS SOCIETY FAVORABLE CONSIDERATION OF THIS BILL. We

have been told by several legislators that they have had no communications from the physicians in their county. While you are writing ask the President, Secretary and other members of your Society to do the same. DON'T PROCRASTINATE, WRITE AT ONCE AND ASK THE OTHERS TO DO THE SAME.

The Esmond bill was reported out of Committee last week and laid aside. It will very likely be on today's calendar for second reading. Senator Wales has introduced Mr Esmond's bill in the Senate.

The Meegan bill defining the practice of medicine as limited to the dispensation of drugs and anesthetics, has been introduced in the Senate by Senator Gibbs.

Mr Hastings has introduced the bandagery bill in the Senate. This bill has not yet been reported out by the Assembly Committee on Public Health, and we hope it will not be.

No other bills have shown any activity during the past week, except Assembly Introductory No 1410, introduced by Mr Thomas relative to the powers and duties of local health boards, has advanced to third reading in the Assembly.

We are enclosing a copy of Assembly Introductory No 1526, the anti-vivisection bill mentioned in Bulletin No 5.

Committee on Legislation

Medical Society of the State of New York

BULLETIN NO 7

March 31, 1926

Our Medical Practice Act was on today's Assembly calendar, but owing to the light attendance of members of the Legislature, due to Holy Week, it has been put over until next Tuesday. Senator Karle, chairman of the Senate Committee on Public Health, will not report the Webb bill out of committee, but will pass it on to the Committee on Rules, which will take charge of all committee work after April 1st.

The Esmond chiropractic bill was on yesterday's calendar, but owing to light attendance, was put over until next Monday night.

Senate Introductory No 921—Karle—concurrent Assembly Introductory No 1267—

Lattin, relative to certificates and reports to be made by counties receiving State aid for public health work, has been passed by the Senate and advanced to third reading in the Assembly.

Senate Introductory No 981—Hewitt—concurrent Assembly Introductory No 1338—Hutchinson, relative to State contributions to counties in aid of public health measures, has passed both Houses and gone to the Governor for signature.

Following is a list of the bills introduced since our last Bulletin.

ASSEMBLY INTRODUCTORY NO 1697

Introduced by Mr Grossman, would amend sections 343-a and 343-b Public Health Law,

State Department of Health

VENEREAL DISEASES REPORTED IN 1925

Syphilis

In 1924 there were thirty-nine fewer new cases of syphilis reported than during the previous year, and it was then thought that it might be that the peak of incidence had been reached and the number of new cases would remain more or less constant for a few years and then decrease. However, the 1925 records show 2,069 more cases than in 1924, an increase of 18 per cent, the largest previous increase in any single year having been 11 per cent. Thus, it would seem that 1924 was not a turning point, but merely a resting point.

The increase in the number of new cases does not necessarily mean an increase in incidence. It may be due to an increased use of laboratories by physicians, an increased vigilance on the part of the profession or an increase in the number of infected persons seeking treatment voluntarily.

Gonorrhea

The number of new cases of gonorrhea reported by laboratories in 1925 was the largest since such statistics have been kept. The reporting of gonorrhea has shown a consistent growth for the past seven years, increasing from 2,447 in 1919 to 4,629 in 1925. The increase last year over the preceding year, nine and one-half per cent, was more than for any previous year.

Diphtheria in 1925

In 1925, 4,370 cases of diphtheria were reported, as compared with 5,883 in 1924. The case rate per hundred thousand population was 90, as compared with the previous lowest rate, 103, in 1908. The mortality rate per hundred thousand population was 69, as compared with the previous low point, 76, in 1924. The fatality rate 77 per 100 cases was higher than any year since 1918, but lower than in any of the years previous to 1919.

PRENATAL CONSULTATIONS IN 1925

During 1925 the Division of Maternity, Infancy and Child Hygiene conducted 208 prenatal consultations in 27 communities, with a total attendance of 1,057. Of these, 474 were new cases and 583 were revisits. An increasing number of physicians attended to consult about their patients. Two hundred and forty-six cases were referred by physicians, as against 91 during the previous year. The majority of cases came under observation during the third or fourth month of pregnancy rather than the seventh or eighth month, as in 1924.

TUBERCULOSIS CLINICS IN 1925

During 1925 the Tuberculosis Division conducted 130 clinics in 26 counties. There were 2,654 patients examined and 816 physicians referred patients. Two hundred and forty-one physicians visited the clinics and many of them assisted in the examination of their patients. When visiting the clinics the physicians have shown a keen interest in its demonstrative characteristics relative to the early diagnosis of diseases of the lungs, and a large number have availed themselves of the opportunity of receiving instructions from the experts conducting the clinics.

The following is a list of some of the non-tuberculous diseases diagnosed at the clinics

Bronchitis	12
Chronic bronchitis	30
Sub-acute bronchitis	6
Acute bronchitis	12
Asthmatic bronchitis	6
Bronchial asthma	46
Bronchiectasis	10
Pleurisy	4
Thickened pleura	9
Emphysema	2
Hydro-pneumothorax	1
Healed pulmonary abscess	1
Pulmonary abscess	2
Pyo-pneumothorax	1
Fibrositis	1
Empyema	1
Curvature of the spine	8
Sprengel's deformity	1
Endocarditis	17
Myocarditis	10
Mitral regurgitation	6
Chorea	1
Thyrototoxicosis	2
Hyperthyroidism	3
Adenomatous goitre	1
Cyst	1
Rickets	1
Pyorrhea	2
Chronically infected tonsils	11
Pharyngitis	2
Chronic valvular disease of the heart	8
Arterio-sclerosis	1
Arthritis deformans	1
Otitis media	1
Lymphatic leukemia	1
Marasmus	1
Umbilical hernia	1
Chronic rheumatoid arthritis	1

been referred to the Assembly Public Health Committee

Senate Introductory No 989-Sheridan—concurrent Assembly Introductory No 1303-Rosenman—requiring the reporting to police authorities of all cases of wounds caused by firearms, passed the Senate and now rests with the Assembly Rules Committee

Senate Introductory No 1295-Dunigan—concurrent Assembly Introductory No 1416-Hofstadter—relating to dental hygienists, has advanced to third reading in the Senate

Assembly Introductory No 1410-Thomas, relative to powers and duties of local health boards, has passed the Assembly and is now with the Committee on Rules in the Senate

Assembly Introductory No 1427-Latin, the nurse registry bill, was advanced in the Assembly to third reading on April 1st

Assembly Introductory No 1700—the Miller

eye bill—has been introduced in the Senate within the last few days by Mr Truman.

HENRY L K SHAW,
ARTHUR W BOOTH,
CLARENCE F GRAHAM,
Committee on Legislation,
Medical Society of the State of New York

P S—The Esmond chiropractic bill came up for second reading Wednesday morning After a short debate, Mr Cuvillier moved to have it recommitted The motion was lost and the bill was advanced to third reading This action must not be interpreted as meaning that the bill has won favor with the Assembly, it is purely a matter of courtesy that a bill as controversial as this should not be deprived of its third reading There is very little doubt but that the bill will be killed when it comes on to the calendar for third reading, which will be Monday or Tuesday

MEDICAL SOCIETY OF THE COUNTY OF QUEENS

The medical Society of the County of Queens held their stated meeting on February 23rd, 1926, President Denis E McMahon in the chair

Four physicians were elected to membership and an equal number received by transfer from other Societies

For the Legislative Committee, Dr T C Chalmers reported on various bills before the legislature and stated that the Medical Practice Act was introduced last Wednesday It is the Medical Practice Act of the State Society At the recent conference of the Legislative Committee, the State Board of Regents and the Special Committee of the State Society, being a body of about 25 men, modifications were adopted, most important of which was the substitution of annual instead of a single registration, but, it was Dr Chalmers' expectation that this would be without the payment of a fee and with the provision that failure to register will not invalidate the right to practice medicine Features of the bill, as now drawn, were explained in detail On motion, consideration of this matter was laid upon the table

Dr E A Fleming for the Committee on Graduate Education called attention to the coming afternoon talks He announced the appropriation of funds for certain activities of the Committee by the Queensboro Tuberculosis Association

In the scientific session, Dr John F Griffin, FACS, of Brooklyn, presented a paper on Urological Aspect of Right Side Pain He stated that the frequency of mistaken diagnosis in conditions that cause right side pain are still common and that many laparotomies are done

before a thorough examination has been made which in obscure cases should include a thorough urinalysis, X-ray and urological investigation A number of conditions found in the right kidney and ureter which simulate closely other intra-abdominal lesions were described, as also the symptoms and differential diagnosis illustrating those conditions with reports of cases coming under the speaker's observation, and particularly emphasizing the frequent errors in diagnosis between appendicitis and some kidney pathology The paper concluded with a statistical report of the cases admitted to St Catherine's Hospital in the past three years with wrong diagnosis, also in the same period of time the number of cases that had had previous operations without relief and the condition as finally diagnosed

Very interesting lantern slides were shown illustrating some of the points brought out in the paper

The discussion was participated in by Doctors McCann, Lent, Krauss, Barber, Dobbins, Rilev Mencken, Mangoni and closed by Dr Griffin

Dr R T Atkins, FACS, of New York presented a paper on Ear, Nose and Throat Complications of Influenza The speaker attributed the occurrence of the various complications described to the secondary infection of the influenza attack He emphasized the occurrence of sinusitis, the involvement of the pharynx and larynx, of the tonsils, the occurrence of cervico-adentitis, of edema of the larynx, of abscesses of the pharynx and trachia, of otitis and of mastoiditis

The discussion was participated in by Doctors Manders, McKay and closed by Dr Atkins

by making provisions for cleanliness in preparation and service of food apply also to drink. Copy of this bill is enclosed.

ASSEMBLY INTRODUCTORY NO 1700 (Concurrent Senate Int No 1413)

Introduced by Mr C P Miller, is a new eye bill to take the place of all of the former eye bills where effort was made to determine the amount of compensation to be paid for an injury to the eye. Copy of this bill is also enclosed.

ASSEMBLY INTRODUCTORY NO 1717 (Concurrent Senate Int No 1338)

Introduced by Mr Rice, would amend the Education Law by providing that one-half the cost of education and surgical treatment of physically handicapped children shall be paid by the county and one-half by the State, and makes an advance appropriation of \$75,000 for the purpose.

ASSEMBLY INTRODUCTORY NO 1776

Introduced by Mr Kennedy, would amend section 310, Public Health Law, by providing a minor whose parent or guardian objects to vaccination of such minor, the compulsory provision therefor shall not apply. When the bill is printed a copy will be forwarded.

* * *

A resolution has been introduced in the Senate by Dr Love, a Senator from Kings County, and referred to the Committee on Finance, providing that a joint legislative committee be created to consist of three members of the Senate and five members of the Assembly, to inquire into and ascertain if public health has been injured by the activity of self-

styled medical institutions and "diploma mills", if graduates of any such low-standard institutions are employed by the State Public Health Service or any other branch of the State government, if graduates of such institutions and "diploma mills" are now practicing medicine in the State of New York, etc. Such committee to choose from its members a chairman, employ a secretary, counsel, stenographers and such other employees and assistants as may be necessary, and fix their compensation. Such committee shall have power to sit within and without the city of Albany, and within and without the State of New York, having authority to subpoena and compel attendance of witnesses, including the production of any book, paper, document or record pertaining to the subject of its investigation and shall have and possess generally all of the powers of a legislative committee.

Such committee shall report to the Legislature of 1927 the result of its findings, together with such remedial legislation as it may deem warranted in suggesting. It is also resolved (if the Assembly concur), that the actual and necessary expenses of the committee in carrying out the provisions of this resolution, not exceeding the sum of \$30,000, be paid from the legislative contingent fund.

HENRY L K SHAW

Medical Society of the State of New York

P S—Senate Introductory No 549—Gibbs—relative to minor surgery, etc for osteopaths, was advanced to third reading today on account of influence of Senator Love.

BULLETIN NO 8

The Medical Practice Act—Assembly Introductory No 955—Loomis, concurrent Senate Introductory No 717—Webb—passed the Assembly yesterday—Tuesday, the 6th—by a vote of 95 to 33, which is the same proportional majority by which the Dunmore bill passed last year. It now goes to the Senate Rules Committee, from which it may be reported this week or early next week.

The Esmond chiropractic bill is on the calendar in the Assembly for second reading today. Probably action will be taken in time to have it appended to this Bulletin.

The osteopathic bill—Senate Introductory No 549, introduced in the Senate by Mr Gibbs, asking for them the privilege of performing minor surgical operations and administering anæsthetics and anti-toxin, was tabled by a vote of 22 to 24. Very likely no effort will be made to take it from the table this year.

The anti-vivisection bill—Assembly Introductory No 1526—Alterman—we have been assured was killed in the Assembly Committee.

The anti-vaccination bill—Assembly Introductory No 1776—Kennedy, concurrent Senate Introductory No 1428—Dunnigan—has made no progress and probably will remain in committee. A copy of the bill is enclosed.

Senate Introductory No 357—Kennedy—concurrent Assembly Introductory No 557—Jenks—habit forming drugs, has been moving in the Senate, but on March 31st was amended and re-committed.

Senate Introductory No 391—Kennedy—concurrent Assembly Introductory No 558—Jenks—Insanity Law, has advanced in the Senate to third reading.

Senate Introductory No 552—Karle—concurrent Assembly Introductory No 417—Jenks—podiatry bill, passed the Senate April 1st and has

been referred to the Assembly Public Health Committee

Senate Introductory No 989-Sheridan—concurrent Assembly Introductory No 1303-Rosenman—requiring the reporting to police authorities of all cases of wounds caused by firearms, passed the Senate and now rests with the Assembly Rules Committee

Senate Introductory No 1295-Dunigan—concurrent Assembly Introductory No 1416-Hofstadter—relating to dental hygienists, has advanced to third reading in the Senate

Assembly Introductory No 1410-Thomas, relative to powers and duties of local health boards, has passed the Assembly and is now with the Committee on Rules in the Senate

Assembly Introductory No 1427-Latin, the nurse registry bill, was advanced in the Assembly to third reading on April 1st

Assembly Introductory No 1700—the Miller

eye bill—has been introduced in the Senate within the last few days by Mr Truman

A resolution has been introduced in the Senate by Dr Love, a Senator from Kings County, and referred to the Committee on Finance, providing that a joint legislative committee be created to consist of three members of the Senate and five members of the Assembly, to inquire into and ascertain if public health has been injured by the activity of self-

styled medical institutions and "diploma mills", if graduates of any such low-standard institutions are employed by the State Public Health Service or any other branch of the State government, if graduates of such institutions and "diploma mills" are now practicing medicine in the State of New York, etc. Such committee to choose from its members a chairman, employ a secretary, counsel, stenographers and such other employees and assistants as may be necessary, and fix their compensation. Such committee shall have power to sit within and without the city of Albany, and within and without the State of New York, having authority to subpoena and compel attendance of witnesses, including the production of any book, paper, document or record pertaining to the subject of its investigation, and shall have and possess generally all of the powers of a legislative committee.

Such committee shall report to the Legislature of 1927 the result of its findings, together with such remedial legislation as it may deem warranted in suggesting. It is also resolved (if the Assembly concur), that the actual and necessary expenses of the committee in carrying out the provisions of this resolution, not exceeding the sum of \$30,000, be paid from the legislative contingent fund.

Medical Society of the State of New York

P S—Senate Introductory No 549—Gibbs—relative to minor surgery, etc., for osteopaths, was advanced to third reading today on account of influence of Senator Love.

BULLETIN NO 8

The Medical Practice Act—Assembly Introductory No 955-Loomis, concurrent Senate Introductory No 717-Webb—passed the Assembly yesterday—Tuesday, the 6th—by a vote of 95 to 33, which is the same proportional majority by which the Dunmore bill passed last year. It now goes to the Senate Rules Committee, from which it may be reported this week or early next week.

The Esmond chiropractic bill is on the calendar in the Assembly for second reading today. Probably action will be taken in time to have it appended to this Bulletin.

The osteopathic bill—Senate Introductory No 549, introduced in the Senate by Mr Gibbs, asking for them the privilege of performing minor surgical operations and administering anæsthetics and anti-toxin, was tabled by a vote of 22 to 24. Very likely no effort will be made to take it from the table this year.

The anti-vivisection bill—Assembly Introductory No 1526-Alterman—we have been assured was killed in the Assembly Committee.

The anti-vaccination bill—Assembly Introductory No 1776-Kennedy, concurrent Senate Introductory No 1428-Dunnigan—has made no progress and probably will remain in committee. A copy of the bill is enclosed.

Senate Introductory No 357-Kennedy—concurrent Assembly Introductory No 557-Jenks—habit forming drugs, has been moving in the Senate, but on March 31st was amended and re-committed.

Senate Introductory No 391-Kennedy—concurrent Assembly Introductory No 558-Jenks—Insanity Law, has advanced in the Senate to third reading.

Senate Introductory No 552-Karle—concurrent Assembly Introductory No 417-Jenks—podiatry bill, passed the Senate April 1st and has

THE DAILY PRESS

MEDICAL PUBLICITY IN ENGLAND

The conservatism of the Medical Profession in England is illustrated by the attitude of the Medical Council, which licenses practitioners of medicine, toward medical publicity. This attitude is described in an item of London news printed in the *New York Sun* of April eighth, which says

"The Council is already under fire because of its ruling that neither a surgeon nor a physician may write a signed article for any newspaper or magazine for the purpose of instructing the general public. It is contended here (in America) that the public is entitled to such information on the subject of keeping well as is given through the newspapers to the American public. Such articles as now appear in the British press, by reason of their anonymity, lack the persuasive power of a signed, authoritative statement, it is held."

The occasion of the article in the *Sun* was the death of Dr F W Axham whose license had been revoked twelve years ago when, at the age of seventy-four, he had given an anesthetic for Sir Herbert Barker, an osteopath, or "Manipulative Surgeon." Barker had received the order of knighthood from the King because of what he had done in the World War, but in spite of the Royal support the medical men refused to recognize him. In describing the dispute between the medical men and Royalty the *Sun* says

"The Council had previously condemned osteopathy as a science and had promulgated a regulation which forbade any practising surgeon or physician to encourage its spread in any way under pain of forfeiting his license. This effectively prevented the spread of osteopathy, inasmuch as people feared to go to an osteopath knowing that if he should fail them, they might not find a medical man willing to receive them back to the true fold. The honor which the King conferred on Sir Herbert could be explained only as a rebuke to the medical council, and was accepted as such by many doctors and laymen."

"It is recognized in the medical world to-day that the council has got itself into an extremely awkward position. All his life it has been the bete noire of the King, who showed it his royal contempt on numerous occasions, not only by conferring knighthood on Barker but by patronizing the late Eugene Sandow, the 'strong man,' after another doctor had lost his license for accepting the position of 'resident physician' of Sandow's famous London 'sanitarium.'"

NURSING

The pastor, next to the physician, is the one best able to give a kindly judgment regarding nurses, for he is the welcomed comforter of the sick and of their anxious families. Dr S Parkes Cadman, Pastor of the Central Congregational Church of Brooklyn, N Y, discusses nurses in his Daily Counsel column of the *New York Herald-Tribune* of March 14th. The question was

"I am a registered nurse and wish to say that some nurses have become so puffed up by the artificial inflation of their educational system as arranged and executed by the regents in certain states that they have lost touch with the humanitarian side of their work."

"They feel that they are protected monopolists. They suffer from white collaritis. They are drawn away from the bedside. They shun fatigue and odors. Instead of combing the hair of patients, they tell them to get it bobbed."

"Will you say something to arouse the community to the necessity of teaching nurses self-denial and faithfulness in disagreeable tasks?"

Dr Cadman replied

"One would prefer to praise and honor the splendid service rendered by nurses rather than criticize them."

"Naturally, with the general tendency in the community to consider one's own comfort and to avoid excessive fatigue and long hours, nurses expect better and easier treatment today than they had hitherto received."

"When the workingman is striking for an eight-hour day and higher wages, the nurse can hardly be expected to remain content to toil from ten to fourteen hours a day for a modest salary."

"Society is beginning to feel as never before the value of the nurse. Because of this she is on the way to becoming a privileged person. It may be hoped that she will not abuse this privilege so long as we set her an example of self-sacrifice and moderation in our own life and practice."

"Few of us are yet in a position to criticize the nurse, for in our daily life we do not commonly measure up to the standard of service and sacrifice which she has attained."

"Such criticism as nurses need may best be given at their own conventions by their own honored leaders and personnel."

"Meanwhile let people who require the services of a trained nurse take care to treat her as a human being."

"She is not a cook, a housemaid but a skilled assistant to the great medical profession."

MEDICAL SOCIETY OF THE COUNTY OF ROCKLAND

At a meeting of the *Comitia Minora* held last month, it was unanimously voted to adopt for our Society the post-graduate education program sponsored by the Committees on Medical Education of the State Society and by the State Department of Health

There will be six lectures in obstetrics on the following subjects I Pre-Natal Care, II Management of Normal Labor, III Post-Partum Care, IV Pathology of Pregnancy, V Pathology of Pregnancy, continued, VI Pathology of Labor These lectures will be given by the following well known obstetricians

Harold C Bailey, M D, New York (Bellevue Hospital), George W Kosmak, M D, New York (Fifth Avenue Hospital), Ralph W Lobenstein, M D, New York, John O Polak, M D, Brooklyn (Long Island College Hosp), James K Quigley, M D, Rochester (Rochester General Hosp), Frederick W Rice, M D, New York (Bellevue Hospital)

This course of lectures will be given in the recreation hall of Summit Park Sanatorium at Summit Park at 3 30 P M on Wednesday afternoons beginning on April 7th

BRONX COUNTY MEDICAL SOCIETY

A regular meeting of the Bronx County Medical Society, held at Concourse Plaza, on March 17, 1926, was called to order at 9 P M, the President, Dr Cuniffe, in the Chair

The following gentlemen were elected as Members of the Nominating Committee Alexander Goldman, Moses H Krakow, Maurice O Magid, Sidney Cohn, Milton R Bookman, Nathan B Jacobson, Henry Roth, Irving Smiley, Martin J Loeb, E John Dolan and Michael Rosenbluth

Election of Candidates being in order, it was moved and carried that the secretary be instructed to cast one ballot for the following candidates for membership Joseph Paul Alvich, A Harry Bussell, Louis A Kapp, Joseph E Feinsot, Benjamin Messinger, Samuel J Miller, Samuel Schecter and Arthur A Traum

The President announced that the meeting of the Medical Society of the State of New York, which is this year held under the auspices of the

Bronx County Medical Society, will take place at the Waldorf-Astoria on March 29th, 30th and 31st He appealed for the cooperation of the members, especially for the banquet, which will be held on March 30th

The Scientific Program proceeded as follows
Paper

"Intestinal Obstruction," John B Deaver

The following doctors participated in the discussion upon the Paper presented by Dr Deaver Drs Henry Roth, J Lewis Amster, L Miller Kahn, Sidney Cohn, Milton R Bookman and Louis Sheinman

Dr Sidney Cohn, in the name of the Bronx Surgical Society, thanked Dr Deaver, and it was moved and carried that the Bronx County Medical Society extend a vote of thanks to Dr Deaver

Respectfully submitted,
I J LANDSMAN, M D, *Secretary*

COURSES IN PUBLIC HEALTH

Physicians who wish to do public health work will be interested in the announcement of summer courses given by the College of Physicians of Columbia University, New York City, under the direction of Dr Haven Emerson, Professor of Public Health

Thirteen courses are announced, each with daily classes, extending from one to five weeks, from July sixth to August thirteenth The courses are as follows

- 1 Public Health — Administration and Rural Hygiene
- 2 Public Health Engineering
- 3 School Health Inspection
- 4 Epidemiology
- 5 Clinics and Health Centers
- 6 Public Health Law
- 7 Industrial Hygiene

- 8 Factory Inspection
- 9 Mental Hygiene
- 10 Social Hygiene
- 11 Child Hygiene
- 12 Tuberculosis
- 13 Introduction to Population and Health Problems

This is the fourth year that the courses have been offered by Columbia University

The courses are so arranged that a student may spend a whole day at the lectures Lectures are given daily in each course in order that a student having a vacation of only a fortnight may complete the courses which he chooses

A prospectus of the courses may be obtained from the College of Physicians and Surgeons, 437 West 59th Street, New York

BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits or in the interests of our readers

- APPLIED BIOCHEMISTRY** By WITHROW MORSE. Octavo of 958 pages with 257 illustrations. Philadelphia and London, W B Saunders Company, 1925 Cloth, \$7.00
- A TEXT-BOOK OF MEDICAL DIAGNOSIS** By JAMES M ANDERS M.D., Ph.D., LL.D., and L. NAPOLEON BOSTON A.M., M.D. Third edition. Octavo of 1422 pages, with 555 illustrations. Philadelphia and London, W B Saunders Company, 1925 Cloth, \$12.00
- THORACIC SURGERY** The Surgical Treatment of Thoracic Disease. By HOWARD LILIENTHAL, M.D., F.A.C.S. Two Octavo volumes totaling 1924 pages, with 904 illustrations. Philadelphia and London, W B Saunders Company, 1925 Cloth, \$20.00
- MASSAGE AND THERAPEUTIC EXERCISE.** By MARY McMILLAN Second Edition. 12mo of 331 pages with 17 illustrations. Philadelphia and London, W B Saunders Company, 1925 Cloth \$2.50
- CHEMICAL PATHOLOGY** Being a Discussion of General Pathology from the Standpoint of the Chemical Processes Involved. By H. GIDEON WELLS, Ph.D., M.D. Fifth Edition. Octavo of 790 pages. Philadelphia and London, W B Saunders Company, 1925 Cloth, \$8.50
- ABDOMINAL AND PELVIC SURGERY FOR PRACTITIONERS** By RUTHERFORD MORISON, Hon.M.A. and D.C.L., Hon. LL.D., M.B., F.R.C.S. 12mo of 212 pages, with illustrations. New York, Oxford University Press, 1925 Cloth, \$2.75 (Oxford Medical Publications)
- POST-MORTEM APPEARANCES** By JOAN M ROSS, M.B., B.S. M.R.C.S., L.R.C.P. 12mo of 216 pages. New York, Oxford University Press, 1925 Cloth, \$2.50 (Oxford Medical Publications)
- SURGICAL CLINICS OF NORTH AMERICA** Volume 5 Number 5 October, 1925 (St. Louis Number) Published every other month by the W B Saunders Company, Philadelphia and London. Per Clinic Year (6 issues) Cloth, \$16.00, Paper, \$12.00
- MEDICAL HEREDITY** Distinguished Children of Physicians (United States, to 1910) By WILLIAM BROWNING Ph.B., M.D. Octavo of 250 pages. Baltimore, The Norman, Remington Company 1925 Cloth, \$4.00
- LIGHT AND HEALTH** A Discussion of Light and Other Radiations in Relation to Life and to Health. By M. LUCKIESH and A. J. PACINI. Octavo of 302 pages illustrated. Baltimore, Williams and Wilkins Company, 1926 Cloth, \$5.00
- PUBLIC HEALTH LAW** A Manual of Law for Sanitarians. By JAMES A. TOBEY M.S. LL.B. Octavo of 304 pages. Baltimore, Williams and Wilkins Company, 1926. Cloth, \$4.50
- A MEDICAL FORMULARY** By E. QUIN THORNTON, M.D. 12th Edition revised. 16mo of 352 pages. Philadelphia and New York, Lea and Febiger 1925 Cloth \$2.50
- PRESCRIPTION NOTES** By ARTHUR L. TAUM 16mo of 22 pages, with blank pages for selected prescriptions. Chicago University of Chicago Press, 1925 Cloth, \$1.25
- OUR PRESENT KNOWLEDGE OF HEREDITY** A Series of Lectures given at the Mayo Foundation and the Universities of Wisconsin, Minnesota, Nebraska, Iowa, and Washington (St. Louis), 1923-1924 12mo of 250 pages illustrated. Philadelphia and London, W B Saunders Company, 1925 Cloth, \$2.50
- LECTURES ON NUTRITION** A Series of Lectures given at the Mayo Foundation and the Universities of Wisconsin, Minnesota, Nebraska, Iowa, and Washington (St. Louis) 1924-1925 12mo of 243 pages, illustrated. Philadelphia and London, W B Saunders Company, 1925 Cloth, \$2.50
- THE MEDICAL CLINICS OF NORTH AMERICA.** Volume 9 Number 4 January, 1926 (Tulane University Number) Published every other month by the W B Saunders Company, Philadelphia and London. Per Clinic Year (6 issues) Cloth, \$16.00, Paper, \$12.00
- ABDOMINAL OPERATIONS** By SIR BERKELEY MOYNIHAN 4th Edition, revised. Two octavo volumes totaling 1217 pages with 470 illustrations, 10 in colors, Philadelphia and London, W B Saunders Company, 1926. Cloth, \$20.00
- MODERN MEDICINE ITS THEORY AND PRACTICE** In Original Contributions by American and Foreign Authors Edited by SIR WILLIAM OSLER, Bart., M.D. F.R.S. Third Edition, thoroughly revised. Re-edited by THOMAS McCRAE, M.D., assisted by ELMER H. FUNK M.D. Volume 2. Octavo of 891 pages illustrated. Philadelphia and New York, Lea and Febiger, 1925 Cloth, \$9.00
- BERGEY'S MANUAL OF DETERMINATIVE BACTERIOLOGY** A Key for the Identification of Organisms of the Class Schizomycetes. By DAVID H. BERGEY Second Edition. Octavo of 462 pages. Baltimore, Williams and Wilkins Company, 1925 Cloth, \$5.50
- MUSCULAR ACTIVITY** By ARCHIBALD VIVIAN HILL, M.A., Sc.D. F.R.S. Octavo of 115 pages, with illustrations. Baltimore, Williams and Wilkins Company 1926. Cloth, \$2.75
- LEAD POISONING.** By JOSEPH C. AUB, LAWRENCE T. FAIRHILL A. S. MINOT, and PAUL REZNIKOFF. Octavo of 265 pages, with illustrations. Baltimore, Williams and Wilkins Company 1926. Cloth, \$4.00 (Medicine Monographs, Volume 7)
- LACTOBACILLUS ACIDOPHILUS** By NICHOLAS KOPELOFF Ph.D. Octavo of 211 pages. Baltimore, Williams and Wilkins Company, 1926 Cloth, \$5.00
- BIRTH CONTROL FACTS AND RESPONSIBILITIES** A Symposium Dealing with this Important Subject from a Number of Angles Edited by ADOLPH MEYER M.D. 12mo of 157 pages. Baltimore, Williams and Wilkins Company, 1925 Cloth, \$3.00
